# Vorwort

Der Rest der Arbeit wird in Englisch sein aber ich habe mich entschieden eine kleine Zusammenfassung zu schreiben, so dass jeder zumindest die Grundlagen meiner Arbeit versteht. Zu begin des 20. Jahrhunderts gab es einen Umschwung in der Physik, Quantenmechanik wurde entdeckt. Diese neue Theorie kann nicht mehr präzise voraussagen machen wie es zuvor der Fall war. Man kann nur noch sagen mit welcher Wahrscheinlichkeit etwas passiert und ein Partikel kann an zwei Orten gleichzeitig sein.

Vielleicht haben Sie schon einmal von Schrödingers Katze gehört. Dies war ein Gedankenexperiment von Schrödinger um auf zu zeigen wie absurd seine Theorie wirklich ist und dass sie nicht stimmen könne. Stell dir vor du schliesst deine Katze in eine Box ein. In dieser Box ist ein Atom das entweder zerfallen kann oder nicht. Dazu gibt es einen Detektor der misst ob das Atom zerfallen ist, in diesem Fall wird ein Gift frei gelassen und die Katze stirbt. Das Problem ist jetzt aber, dass dieses Atom den Regeln der Quanten Mechanik folgt und deshalb gleichzeitig bereits zerfallen ist und nicht zerfallen ist, die einzig logische Schlussfolgerung ist deshalb, dass *die Katze gleichzeitig Tod und am leben ist* (Schrödinger, 1935).

In der Realität funktioniert es wahrscheinlich jedoch nicht so. Heisst das Universum “entscheidet” ob die Katze gestorben ist oder nicht, jedoch weiss man bis Heute nicht wann das Universum “entscheidet”.

Damit die Katze gleichzeitig Tod und Lebendig sein kann brauchen wir die Wellenfunktion. Sie beschreibt alles was in unserem Universum gerade passiert und “speichert” wie wahrscheinlich es ist, dass die Katze tot ist.

In meiner Maturaarbeit habe ich ein Programm geschrieben das genau diese Wellenfunktion ausrechnet in einem sehr vereinfachten Universum. Weil ich schon lange mal wissen möchte wie genau dieses bizarre Objekt aussieht. Auf der Titel Seite ist eine dieser Wellenfunktionen abgebildet.

# 1. Introduction

Richard Feynmann one of the core people behind our modern theory of quantum mechanics repeatedly said: “I think I can safely say that nobody understands quantum mechanics.”. Nothing behaves like in our every day lives. Everything is just a probability and nothing certain. Even Schrödinger the inventor of the equation that governs all of those weird phenomena rejected the idea that there are just probabilities.

In this paper we will try to understand this world a little bit better by looking at wave functions in a simplified universe. This universe only has 1 dimension and there will not be any sense of time. This means we will be able to actually see how the wave function looks like in a graph.

## 1.1. Goals

The goal of this Maturaarbeit is to write a program, `schroeding-approx` that calculates solutions to the time independent Schrödinger equation in 1 dimension for a large variety of potentials. We assume that the wave function,  $\Psi(x)$  will converge to 0 as  $x$  goes to  $\pm\infty$ . The program should be reasonably fast, meaning that for simple potentials and low energies it should be done in under 1 minute. The architecture should be able to support improvements.

Making the program user friendly is not a main focus. Meaning that a clear and simple API that can be extended in the future is enough. Even though the user will have to edit the code to for example change between energies.

The program should also follow the UNIX philosophy, “do one thing and one thing well”. As a consequence the program will only do the calculations and not the plotting. But it provides a simple and clear interface for a plotting program such as GNU Plot.

The main focus will be to balance performance and accuracy. Accuracy mainly meaning that the visualizations should be visually accurate and give some insight into quantum mechanics. The user should also be able to tune the balance between performance and accuracy to some degree.

## 2. Preliminary

### 2.1. Schrödinger Equation

In 1926 Erwin Schrödinger changed our understanding of quantum physics with the Schrödinger equation. Based on the observations of de Broglie that particles behave like waves he developed a wave equation which describes how the waves move and change in a given potential  $V(x)$  or Hamiltonian  $\hat{H}$ .

$$i\hbar \frac{\partial}{\partial t} \Psi(x, t) = \left[ -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + V(x, t) \right] \Psi(x, t)$$

Or more general

$$i\hbar \frac{\partial}{\partial t} \Psi(x, t) = \hat{H} \Psi(x, t)$$

The time independent version that is going to be used later, ignores the change over time and is much simpler to solve since it is **only** an ordinary differential equation instead of a partial differential equation.

$$E\psi(x) = \hat{H}\psi(x)$$

or

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2}(x) + V(x)\psi(x) = E\psi(x)$$

Even with the time independent equation it is very difficult to get analytical solutions, because of this there are mainly three approaches to approximate solutions of  $\psi(x)$ , perturbation theory, density functional field theory and WKB approximation. Perturbation theory's goal is to give an analytical approximation which means it is extremely difficult to implement for a computer. WKB on the other hand is much better since it is to some degree a step by step manual.

### 2.2. Rust

Rust is one of the newer programming languages and attempts to replace C/C++ which are notoriously difficult to work with. It supports both functional and object-oriented paradigms. It is much safer in terms of memory and promises the same performance as C. One of the goals of Rust is fearless concurrency which means everybody should be able to write concurrent

code without deadlocks and data races. This means calculations can utilize the full potential of the CPU without countless hours of debugging.

Functional programming languages are especially useful for mathematical problems, because they are based on the same mathematics as the problem.

Rust as of the time of writing this document is not yet standardized meaning the code provided might no longer be correct with one of the newer Rust versions.

In case you aren't familiar with Rust, it has excellent documentation on <https://doc.rust-lang.org/book/>.

## 2.3. Interpretation of Quantum Mechanics

The author believes in the many worlds interpretation of Hugh Everett. *“The wave interpretation. This is the position proposed in the present thesis, in which the wave function itself is held to be the fundamental entity, obeying at all times a deterministic wave equation.”* (DeWitt und Graham, 2015, p. 115). This means that the observer is also quantum mechanical and gets entangled with one particular state of the system that is being measured (DeWitt und Graham, 2015, p. 116). This is some what different to the popular explanation of many worlds but has the same results and is, at least to the author more reasonable.

An important point for the author also was that the theory accepts quantum mechanics as it is and doesn't make unreasonable assumption such as that the observer plays an important role.

On top of that this interpretation also discards the need for an “observation” in the program which would also be mathematically impossible (DeWitt und Graham, 2015, p. 111).

## 2.4. Complex Numbers

In quantum mechanics it's customary to work with complex numbers. Complex numbers are an extension to the real numbers, since Rust will do most of the heavy lifting here are the most important things that you should know

$$i^2 = -1$$

$$z = a + bi$$

$$\operatorname{Re}(z) = a$$

$$\operatorname{Im}(z) = b$$

$$\bar{z} = a - bi$$

$$\|z\|^2 = a^2 + b^2$$

$$e^{\theta i} = \cos(\theta) + i\sin(\theta)$$

$i$  is the imaginary unit,  $z$  is the general form of a complex number where  $\{a, b\} \in \mathbb{R}$ ,  $\bar{z}$  is the complex conjugate and  $\|z\|^2$  is the norm square of  $z$ . The last equation is the Euler's formula, it rotates a number in the complex plane by  $\theta$  radians.

The complex plane is similar to the real number line, every complex number can be represented on this plane where  $\text{Re}(z)$  is the x-coordinate and  $\text{Im}(z)$  is the y-coordinate.

## 2.5. Gnuplot

Gnuplot is a cross platform plotting program that is very simple to use. `schroedinger-approx` will output a file `data.txt`, you can plot the function by typing `gnuplot` and then typing

```
1 call "plot.gnuplot"
```

to plot the real part of the wave function, or

```
1 call "plot_3d.gnuplot"
```

to see the full complex wave function.

If you'd like to learn more about Gnuplot you can read there user manual on <http://www.gnuplot.info/>

## 2.6. Reading Complex Plots

In the case of this paper we will try to plot a function

$$f : \mathbb{R} \rightarrow \mathbb{C}.$$

This means that the resulting plot will be 3 dimensional. The two main visualizations would be just to plot a 3D surface or add the phase of the complex number as a color. The first method works better if one can interact with the structure. However this is not really possible in a PDF or on a paper. This is why both options will be implemented.

For example on the next page you have the plot from the title page as a 3D plot in comparison to the color plot.

Figure 2.1.: 3D plot of super position of  $V(x) = x^2$  and energies 9, 12 and 15

Figure 2.2.: Color plot of super position of  $V(x) = x^2$  and energies 9, 12 and 15

As we can see the 3D plot is basically unusable since there is no depth and lighting would also be very difficult to do on a line such that we could actually see the depth. In the color plot every thing seems to be clear. Except that the values of the phase can't be read exactly.

When plotting the function yourself I would still recommend the 3D plot because it's clearer when you can move it around.

To get used this representation, have a look at figure 2.6.

Figure 2.3.: Illustration of the mapping of an angle to color to represent complex numbers

Here we can see that we can assign a color to every argument of a complex number can be assigned a distinct color. For example  $1 + 0i$  would have the color cyan and  $0 + 1i$  would be purple. This graph is a handy tool to read the color plots that will be done later since it's easier to associate the angle with the color if the color is actually at that angle rather than displaying it radians.

## 2.7. Planck Units

By using Planck units the equations get a little bit easier. Working in Planck units means that all fundamental constants are equal to 1.

$$c = k_B = G = \hbar = 1.$$

This means that the constants will usually cancel out.

To convert to SI units we can just multiply powers of the constants such that there unit results in one of the base units.

$$\begin{aligned} l_{\text{Planck}} &= l_{\text{SI}} \sqrt{\frac{G\hbar}{c^3}} & 1 \text{ m}_{\text{Planck}} &\approx 1.616255(18) \cdot 10^{-35} \text{ m} & (\text{CODATA, 2022a}) \\ m_{\text{Planck}} &= m_{\text{SI}} \sqrt{\frac{c\hbar}{G}} & 1 \text{ kg}_{\text{Planck}} &\approx 2.176434(24) \cdot 10^{-8} \text{ kg} & (\text{CODATA, 2022b}) \\ t_{\text{Planck}} &= t_{\text{SI}} \sqrt{\frac{G\hbar}{c^5}} & 1 \text{ s}_{\text{Planck}} &\approx 5.391247(60) \cdot 10^{-44} \text{ s} & (\text{CODATA, 2022c}) \end{aligned}$$

(Gaarder Haug, 2016, Table 1)

The program will take all of its in- and outputs in Planck units.

## 3. Methods

### 3.1. Program Architecture

The program has multiple interfaces or traits as they are called in Rust that give the program some abstraction. In Appendix C is a UML diagram of the architecture. Since current version of Rust does not support manual implementations of `std::ops::Fn` we have to define our own trait for functions `Func<A, R>` where A is the type of the argument and R is the return type. Later we will use this trait to implement functions for integration, evaluation and more useful utilities.

`WaveFunction` is at the heart of the program, it contains all the functionality to build wave functions. It is composed of `WaveFunctionPart` which represent either a `Joint`, `PureWkb` or an `ApproxPart`. With the `range` function we can check when they are valid.

### 3.2. Newtons Method

Newton's method, also called the Newton-Raphson method, is a root-finding algorithm that uses the first few terms of the Taylor series of a function  $f(x)$  in the vicinity of a suspected root (Weisstein, 2022). It makes a sequence of approximations of a root  $x_n$  that in certain cases converges to the exact value where

$$\lim_{n \rightarrow \infty} f(x_n) = 0$$

The sequence is defined as

$$x_0 = a$$
$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

Visually this looks like figure 3.1 where  $f(x) = (x-2)(x-1)(x+1)$  was taken as an example.

Figure 3.1.: Illustration of Newtons method,  $f(x) = (x - 1)(x - 2)(x + 1)$ .

The blue line indicates the initial guess which in this case is 2.5 the black line ( $g(x)$ ) is a tangent to  $f(x)$  at  $(guess, f(guess))$  the next guess will be where the tangent intersects the x-Axis (solution of  $g(x) = 0$ ). This will converge rather quickly compared to other methods such as Regula falsi.

```

1 pub fn newtons_method<F>(f: &F, mut guess: f64, precision: f64) -> f64
2     where
3         F: Fn(f64) -> f64,
4     {
5         loop {
6             let step = f(guess) / derivative(f, guess);
7             if step.abs() < precision {
8                 return guess;
9             } else {
10                 guess -= step;
11             }
12         }
13     }

```

In Rust the sequence is implemented with a function that takes a closure  $f$ , the initial guess  $guess$  and a stop condition  $precision$  the function will return if  $\|cf rac{f(x_n)}{f'(x_n)}\|$  is less than  $precision$ .

From the structure of the algorithm it is very tempting to implement it recursively, but by using a loop it is much faster since there are no unnecessary jumps and the precision can (at least in theory) be 0 without causing a stack overflow.

### 3.3. Regula Falsi with Bisection

Newtons method fails if the first guess is at a maximum, since the step would go to infinity. For this case we can first use a bisection search to detect a sign change. We need to do a bisection search since Regula falsi requires two guesses.

The algorithm itself is quite simple. To start we need

$$f(x) : \mathbb{R} \rightarrow \mathbb{R} \quad (3.1)$$

$$\{a \in \mathbb{R} \mid f(a) \leq 0\} \quad (3.2)$$

$$\{b \in \mathbb{R} \mid f(b) \geq 0\}. \quad (3.3)$$

Then we can draw a line between the two points  $(a, f(a))$  and  $(b, f(b))$ . Then  $a$  becomes the x-value where the line intersects the x-axis becomes the new  $b$ , when we do the process again with the new  $b$  we will get our new value for  $a$ . We can repeat this process until we cross a fresh hold for the accuracy and the result will be the last inter section of the line with the x-axis.

### 3.4. Derivatives

Derivatives can be calculated numerically as in the C++ library Boost (John Maddock, 2022). The author implemented a analytical system for derivatives in Go. From that experience the benefit is negligible compared to the increase in performance and in development time since every function is a special object.

```
1 pub fn derivative<F, R>(func: &F, x: f64) -> R
2 where
3     F: Fn(f64) -> R + ?Sized,
4     R: Sub<R, Output = R> + Div<f64, Output = R> + Mul<f64, Output = R> + Add<R,
        Output = R>,
5 {
6     let dx = f64::epsilon().sqrt();
7     let dx1 = dx;
8     let dx2 = dx1 * 2.0;
9     let dx3 = dx1 * 3.0;
10
11     let m1 = (func(x + dx1) - func(x - dx1)) / 2.0;
12     let m2 = (func(x + dx2) - func(x - dx2)) / 4.0;
13     let m3 = (func(x + dx3) - func(x - dx3)) / 6.0;
14
15     let fifteen_m1 = m1 * 15.0;
16     let six_m2 = m2 * 6.0;
17     let ten_dx1 = dx1 * 10.0;
18
19     return ((fifteen_m1 - six_m2) + m3) / ten_dx1;
20 }
```

`f64::epsilon().sqrt()` is approximately 0.000000014901161. `f64::epsilon()` is the smallest double precision floating point number where  $1 + \epsilon \neq 1$ . this has been chosen for  $dx$  because it should be fairly precise.

### 3.5. Integration

The same principles apply to integrals as to derivative it would not be a great benefit to implement an analytic integration system. Integrals would also be much more difficult to implement than derivatives since integrals can not be broken down in to many smaller integrals that can be computed easily instead it needs to be solved as is.

One approach would be to use the same method as with the derivative, take the definition with the limit and use a small value but this method can be improved in this case, since integrals calculate areas under curves a trapeze is more efficient and accurate then the rectangle that results from the definition.

Figure 3.2.: Illustration of integration with trapeze from Wikipedia (2022).

Figure 3.2 shows visually how the methods work, each blue trapeze from start ( $a$ ) to end ( $b$ ) has an area of

$$\int_a^b f(x) dx \approx (b-a)f\left(\frac{a+b}{2}\right).$$

One trapeze would be fairly inaccurate to calculate the area under the function but as the area from  $a$  to  $b$  is subdivided further the result become better and better.

The general structure of the algorithm can very easily be run in parallel since it doesn't matter in which order the segments are added together and the segments also don't dependent on one another. In Rust this is implemented using rayon. Rayon is an implementation for parallel iterators meaning that normal data structures that implement `std::iter` can be run in parallel *just* by changing `::iter()` to `::par_iter()`. This might not work in all cases because of memory safety but in this case the borrow checker will throw an error and the code wont compile.

```
1 pub trait Func<A, R>: Sync + Send {
2     fn eval(&self, x: A) -> R;
3 }
4
5 pub struct Point {
6     pub x: f64,
```

```

7   pub y: Complex64,
8 }

```

Such that functions with states, like wave functions that store parameters, can be integrated there is a trait `Func<A, R>`.

`Point` stores both the input, `x` and the output, `y` of a function.

```

1 pub fn evaluate_function_between<X, Y>(f: &dyn Func<X, Y>, a: X, b: X, n: usize) ->
   Vec<Point<X, Y>>
2 where
3     X: Copy
4         + Send
5         + Sync
6         + std::cmp::PartialEq
7         + From<f64>
8         + std::ops::Add<Output = X>
9         + std::ops::Sub<Output = X>
10        + std::ops::Mul<Output = X>
11        + std::ops::Div<Output = X>,
12     Y: Send + Sync,
13 {
14     if a == b {
15         return vec![];
16     }
17
18     (0..n)
19         .into_par_iter()
20         .map(|i| {
21             index_to_range(
22                 X::from(i as f64),
23                 X::from(0.0_f64),
24                 X::from((n - 1) as f64),
25                 a,
26                 b,
27             )
28         })
29         .map(|x: X| Point { x, y: f.eval(x) })
30         .collect()
31 }

```

`Func<X, Y>` can be passed to `evaluate_function_between` it calculates `n` points between an interval from `a` to `b` and returns a vector of `Point`. `X` and `Y` are general data types such that it supports as many types of numbers as possible.

```

1 pub fn integrate<
2   X: Sync + std::ops::Add<Output = X> + std::ops::Sub<Output = X> + Copy,
3   Y: Default
4     + Sync
5     + std::ops::AddAssign
6     + std::ops::Div<f64, Output = Y>
7     + std::ops::Mul<Output = Y>
8     + std::ops::Add<Output = Y>
9     + Send
10    + std::iter::Sum<Y>
11    + Copy
12    + From<X>,
13 > (
14   points: Vec<Point<X, Y>>,
15   batch_size: usize,
16 ) -> Y {
17   if points.len() < 2 {
18     return Y::default();
19   }
20
21   let batches: Vec<&[Point<X, Y>]> = points.chunks(batch_size).collect();
22
23   let parallel: Y = batches
24     .par_iter()
25     .map(|batch| {
26       let mut sum = Y::default();
27       for i in 0..(batch.len() - 1) {
28         sum += trapezoidal_approx(&batch[i], &batch[i + 1]);
29       }
30       return sum;
31     })
32     .sum();
33
34   let mut rest = Y::default();
35
36   for i in 0..batches.len() - 1 {
37     rest += trapezoidal_approx(&batches[i][batches[i].len() - 1], &batches[i + 1][0]);
38   }
39
40   return parallel + rest;
41 }

```

The actual integration happens in `integrate`, it calculates the areas of the trapezes between the points passed to it. For optimization 1000 trapezes are calculated per thread because it would take more time to create a new thread then to actually do the calculation, this has to be further investigated and 1000 might not be optimal. The calculations performed per thread are called a batch, after all batches have been calculated the boundaries between batches also has to be considered therefor they are added in the end with `rest`.

### 3.6. Transition Regions

The approximation that will be used splits  $\Psi(x)$  into multiple parts that do not match perfectly together.

Figure 3.3.: Example for joining functions

Lets consider an example, in figure 3.6 we can see two Taylor series of cosine. Now we have to join the two functions at  $x = \pi/2$  such that its a mathematically smooth transition.

$$f(x) = 1 - \frac{x^2}{2} \quad (3.4)$$

$$g(x) = \frac{(x - \pi)^2}{2} - 1 \quad (3.5)$$

As a first guess lets join  $f(x)$  and  $g(x)$  with a step function, this means that the joint function  $h(x)$  will be

$$h(x) = \begin{cases} f(x) & x < \frac{\pi}{2} \\ g(x) & x > \frac{\pi}{2} \end{cases}.$$

This gives us 3.6 which is obviously not smooth.

Figure 3.4.: Plot of  $h(x)$  with step joint

If we use the formula from (Hall, 2013, p. 325, section 15.6.4) with

$$\begin{aligned}\delta &= 0.5 \\ \alpha &= \frac{\pi}{2} - \frac{\delta}{2} \\ \chi(x) &= \sin^2\left(x \frac{\pi}{2}\right)\end{aligned}$$

this results in

$$h(x) = \begin{cases} f(x) & x < \alpha \\ g(x) & x > \alpha + \delta \\ f(x) + (g(x) - f(x))\chi\left(\frac{x - \alpha}{\delta}\right) & \text{else} \end{cases}$$

which is mathematically smooth as we can see in figure 3.6 (proof in Appendix A.1.1).

Figure 3.5.: Plot of  $h(x)$  with Hall joint

### 3.6.1. Implementation in Rust

In the program we can define a struct `Joint` that implements `Func<f64, Complex64>`. As in the example we need two functions  $f(x)$  and  $g(x)$  which we will rename to `left` and `right`. We will also need a variable  $\alpha$  and  $\delta$  which will be named `cut` and `delta`.

```

1  #[derive(Clone)]
2  pub struct Joint {
3      pub left: Arc<dyn Func<f64, Complex64>>,
4      pub right: Arc<dyn Func<f64, Complex64>>,
5      pub cut: f64,
6      pub delta: f64,
7  }
8
9  impl Func<f64, Complex64> for Joint {
10     fn eval(&self, x: f64) -> Complex64 {
11         let chi = |x: f64| f64::sin(x * f64::consts::PI / 2.0).powi(2);
12         let left_val = left.eval(x);
13         return left_val + (right.eval(x) - left_val) * chi((x - self.cut) / self.
            delta)
14     }

```

15 }

In the proof we assume that  $f(x)$  and  $g(x)$  are continuous of first order in the interval  $(\alpha, \alpha + \delta)$ . In the code we will not check this requirement since it would have a major impact on performance to check the derivative on every point.

## 4. Calculation

### 4.1. Energy Levels

Solving the Schrödinger equation is an eigenvalue problem. This means that only certain energies will result in physically correct results. For an energy to be valid it has to satisfy the Maslov-corrected Bhor-Sommerfeld condition which states that

$$n \in \mathbb{N}_0 \quad (4.1)$$

$$C = \{x \in \mathbb{R} \mid V(x) < E\} \quad (4.2)$$

$$\int_C \sqrt{2m(E - V(x))} dx = 2\pi(n + 1/2) \quad (4.3)$$

this condition does not (in most cases) give the exact energy levels (Hall, 2013). It can be interpreted such that the oscillating part of the wave function has to complete all half oscillation.

To solve this problem for an arbitrary potential in a computer the set  $C$  and the fact that  $n$  has to be a non negative integer is not really helpful, but the condition can be rewritten to

$$p(x) = \begin{cases} \sqrt{2m(E - V(x))} & V(x) < E \\ 0 & \text{else} \end{cases} \quad (4.4)$$

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} p(x) dx - \frac{1}{2} \bmod 1 = 0 \quad (4.5)$$

Unfortunately 4.5 is not continuous which means that Newtons method can't be applied. Further on the bounds of integration have to be finite, this means the user of the program will have to specify a value for the constant APPROX\_INF where any value for  $x$  out side of that range should satisfy  $V(x) > E$ . But it shouldn't be to big since the integrate function can only evaluate a relatively small number (default 64000) of trapezes before the performance will suffer enormously. The default value for APPROX\_INF is  $(-200.0, 200.0)$ .

The implementation is quite strait forward we evaluate 4.5 for a number of energies and then check for discontinuities.

```
1 pub fn nth_energy<F: Fn(f64) -> f64 + Sync>(n: usize, mass: f64, pot: &F, view: (f64, f64)) -> f64 {
2     const ENERGY_STEP: f64 = 10.0;
3     const CHECKS_PER_ENERGY_STEP: usize = INTEG_STEPS;
4     let sommerfeld_cond = SommerfeldCond { mass, pot, view };
5
6     let mut energy = 0.0;
7     let mut i = 0;
```

```

8
9     loop {
10         let vals = evaluate_function_between(
11             &sommerfeld_cond,
12             energy,
13             energy + ENERGY_STEP,
14             CHECKS_PER_ENERGY_STEP,
15         );
16         let mut int_solutions = vals
17             .iter()
18             .zip(vals.iter().skip(1))
19             .collect::<Vec<&Point<f64, f64>>>>()
20             .par_iter()
21             .filter(|(p1, p2)| (p1.y - p2.y).abs() > 0.5 || p1.y.signum() != p2.y.
22                 signum())
23             .map(|ps| ps.1)
24             .collect::<Vec<&Point<f64, f64>>>>();
25         int_solutions.sort_by(|p1, p2| cmp_f64(&p1.x, &p2.x));
26         if i + int_solutions.len() > n {
27             return int_solutions[n - i].x;
28         }
29         energy += ENERGY_STEP - (ENERGY_STEP / (CHECKS_PER_ENERGY_STEP as f64 + 1.0))
30         ;
31         i += int_solutions.len();
32     }
33 }

```

First we check over the interval  $(0.0, \text{ENERGY\_STEP})$  if there are not enough zeros we check the next interval of energies and so on until we found  $n$  zeros. It's also possible that 4.5 is negative before the 0th energy there for we also have to check for normal zeros by comparing the signs of the values.

The struct `SommerfeldCond` is a `Func<f64, f64>` that evaluates 4.5.

#### 4.1.1. Accuracy

For a benchmark we will use

$$\begin{aligned}
 m &= 1 \\
 V(x) &= x^2 \\
 (-\infty, \infty) &\approx (-200, 200).
 \end{aligned}$$

To get the actual values we will use Wolfram Language with WolframScript a programming language similar to Wolframalpha that can calculate the integral analytically. In Rust we can rewrite main to

```

1 fn main() {
2     let output_dir = Path::new("output");
3 }

```

```

4     let values = (0..=50)
5       .into_iter()
6       .map(|n: usize| Point::<usize, f64> {
7         x: n,
8         y: energy::nth_energy(n, 1.0, &potentials::square, APPROX_INF),
9       })
10      .collect::<Vec<Point<usize, f64>>>();
11
12      std::env::set_current_dir(&output_dir).unwrap();
13      File::create("energy.txt")
14        .unwrap()
15        .write_all(plot::to_gnuplot_string(values).as_bytes())
16        .unwrap();
17  }

```

This will output all energy levels from  $n = 0$  to  $n = 50$ . We can implement the same thing in WolframScript

```

1  m = 1
2  V[x_] = x^2
3
4  nthEnergy[n_] = Module[{energys, energy},
5    sommerfeldIntegral[en_] = Integrate[Sqrt[2*m*(en - V[x])],
6                                         {x, -Sqrt[en], Sqrt[en]}]
7    energys = Solve[sommerfeldIntegral[en] == 2*Pi*(n + 1/2), en] // N;
8    energy = en /. energys[[1]];
9    energy
10   ]
11
12  energys = Table[{n, N@nthEnergy[n]}, {n, 0, 50}]
13
14  csv = ExportString[energys, "CSV"]
15  csv = StringReplace[csv, "," -> " "]
16  Export["output/energies_exact.dat", csv]

```

These programs will output two files `energies_approx.dat` (Appendix B.1) for our implementation in Rust and `energies_exact.dat` (Appendix B.1) for WolframScript. As a rough estimate we would expect an error of  $\pm \frac{10}{64000} \approx \pm 1.56 \cdot 10^{-4}$ , because the program checks for energies with that step size.

Figure 4.1.: Absolute error of energy levels in square potential

When we plot the absolute error we get figure 4.1.1. The error is a little higher than expected which is probably due to errors in the integral. Still the algorithm should be precise enough. If you'd like you could pick a lower value for `ENERGY_STEP` in `src/energy.rs:49`, but this will impact the performance for calculating energies with higher numbers for  $n$ .

## 4.2. Approximation Scheme

There are mainly three approximation methods used to solve for the actual wave function itself. There is perturbation theory which breaks the problem down in to ever smaller sub-problems that then can be solved exactly. This can be achieved by adding something to the Hamiltonian operator  $\hat{H}$  which can then be solved exactly. But *perturbation theory is inefficient compared to other approximation methods when calculated on a computer* (Van Mourik et al., 2014, Introduction).

The second is Density functional field theory, it has evolved over the years and is used heavily in chemistry to calculate properties of molecules and is also applicable for the time dependent Schrödinger equation. It is something that might be interesting to add to the program in the future.

The program uses the third method WKB approximation, it is applicable to a wide verity of linear differential equations and works very well in the case of the Schrödinger equation. Originally it was developed by Wentzel, Kramers and Brillouin in 1926. It gives an approximation to the eigenfunctions of the Hamiltonian  $\hat{H}$  in one dimension. The approximation is best understood as applying to a fixed range of energies as  $\hbar$  tends to zero (Hall, 2013,

p. 305).

WKB splits  $\Psi(x)$  into tree parts that can be connected to form the full solution. The tree parts are described as

$$p(x) = \sqrt{2m(|E - V(x)|)} \quad (4.6)$$

$$V(t) - E = 0 \quad (4.7)$$

$$\psi_{exp}^{WKB}(x) = \frac{c_1}{2\sqrt{p(x)}} \exp\left(-\left|\int_x^t p(y)dy\right|\right) \quad (4.8)$$

$$\psi_{osc}^{WKB}(x) = \frac{c_1}{\sqrt{p(x)}} \cos\left(\int_x^t p(y)dy + \delta\right) \quad (4.9)$$

$$u_1 = -2m \frac{dV}{dx}(t) \quad (4.10)$$

$$\psi^{Airy}(x) = \frac{c_1 \sqrt{\pi}}{\sqrt[6]{u_1}} \text{Ai}\left(\sqrt[3]{u_1}(t-x)\right). \quad (4.11)$$

Since equation 4.7 might have more than one solution for turning points  $t$ , we have to consider each one of them individually and in the end join them into one function.

The factor of  $1/2$  in equation 4.8 is analogous to (Littlejohn, 2020, eq. 92). This means that it's only valid if the turning points aren't "too close together" (Littlejohn, 2020). This will be a problem later when we look at some solutions. Littlejohn (2020) also mentions that there are extensions to WKB that can handle these cases. It would be interesting to add those to the program in the future.

Unfortunately there seems to be some kind of error in equation 4.9 when two different turning points are used the result at least according to Hall (2013) should be the same. But there functions did not join nicely in the middle of the two turning points. To maintain smoothness only one turning point was there for used. This issue will be discussed later in section 4.5.

Figure 4.2.: Left half of wave function with  $N_{Energy} = 9 \Rightarrow E \approx 13.4$ ,  $m = 2$ ,  $V(x) = x^2$

In figure 4.2 the three parts are visualized. The purple section on the left is the exponential decaying part  $\psi_{exp}^{WKB}(x)$ , equation 4.8 is calculated according to (Hall, 2013, p. 317, Claim 15.7) where  $b$  and  $a$  are different solutions for  $t$  of equation 4.7. The absolute symbol makes it possible to not differentiate between the case where  $x < t$  and  $x > t$ .

#### 4.2.1. Validity

When we look at the derivation of WKB we will see that equations 4.8 and 4.9 can only be valid if

$$p(x) = \sqrt{V(x) - E}$$

$$\left| \frac{dp}{dx}(x) \right| \ll p^2(x)$$

as Zwiebach (2018) showed in his lecture. But this would mean that WKB is only valid iff  $V(x) > E$  because  $p^2(x)$  would be negative otherwise. If this is the case this would imply that 4.8 can't be valid.

We will assume that this contradiction is wrong and assume that WKB is valid if

$$\left| \frac{d}{dx}(\sqrt{|V(x) - E|}) \right| < |V(x) - E|$$

### 4.2.2. Implementation

#### WKB

`WkbWaveFunction` implements equations 4.8 and 4.9. For this we will create two functions `psi_osc` and `psi_exp`. We will use `psi_osc` if `x` is inside the classically allowed region and otherwise we will use `psi_exp`.

```
1 fn eval(&self, x: f64) -> Complex64 {
2     let val = if self.phase.energy < (self.phase.potential)(x) {
3         self.psi_exp(x)
4     } else {
5         self.psi_osc(x)
6     };
7
8     return (self.op)(val);
9 }
```

The term `self.op` has been an attempt to use both turning points for the oscillating region. It wasn't removed because the current method is not perfect either and it can be used in the future to improve the accuracy.

In the exponential part we will always use the corresponding turning point and because we're working with two separate turning points in the same function it is possible that the sign of the exponential part doesn't match with the sign of the exponential part. To fix this, we can define the `get_exp_sign` function.

```
1 pub fn get_exp_sign(&self) -> f64 {
2     let limit_sign = if self.turning_point_exp == self.turning_point_osc {
3         1.0
4     } else {
5         -1.0
6     };
7
8     (self.psi_osc(self.turning_point_exp + limit_sign * f64::EPSILON.sqrt()) / self.c
9         .re
10        .signum())
11 }
```

It calculates the limit of the sign of the oscillating region as `x` approaches the turning point.

$$\text{sgn}\left(\lim_{x \rightarrow t^{\pm}} \psi_{osc}^{WKB}(x)\right)$$

## Airy

The constructor `AiryWaveFunction::new` calculates all the turning points in the view and then creates an `AiryWaveFunction` for each of them. These functions are then returned as a pair of the instance and the corresponding turning point.

Just like in the case of the WKB functions, the Airy implementation also implements the `self.op` which can be used to implement the osculating region with two turning points

### 4.3. Turning Points

A point  $x$  where  $V(x) = E$  is called a turning point. We assume that the WKB function is a good approximation in the region where

$$-\frac{1}{2m} \frac{dV}{dx}(x) \ll (V(x) - E)^2. \quad (4.12)$$

In order to do the actual calculation we need a range where the Airy function is valid. From equation 4.12 we can infer that the Airy function is valid where

$$-\frac{a}{2m} \frac{dV}{dx}(x) - (V(x) - E)^2 > 0 \quad (4.13)$$

We can assume that the Airy function is only valid in a closed interval, this means that there must be at least two roots of equation 4.13. These roots will be called turning point boundaries from now on. The factor of  $a$  is used to emulate the behavior of  $\ll$ .

The left boundary point must have a positive and the right a negative derivative. This means we can solve for roots and group them together by their derivatives. In order to find all roots we will use a modification of Newton's method. When we find a solution,  $x_0$  we can divide the original function by  $(x - x_0)$  this means that Newton's method won't be able to find  $x_0$  again.

To later plot the wave function we will define the so called "view". This is the interval which the user will see in the end. It is defined to be

$$(t_l - f_{view}(t_r - t_l), t_r - f_{view}(t_r - t_l))$$

where  $t_l$  is the left and  $t_r$  the right most turning point.  $f_{view}$  is a user defined constant. These two points will be calculated by applying Newton's method to  $V(x) - E$  with initial guesses at `APPROX_INF`.

Further on since we check for roots inside the interval of the view, we don't have a good first guess where the turning point might be. Because of this we will make 1000 guesses evenly distributed over the interval and invent a system that can rate how good of a guess this point could be. Newton's method works well if the value of  $f(x)$  is small and  $f'(x)$  is neither too small nor too big. We will assume that  $f'(x) = 1$  is optimal. As a rating we will use

$$\sigma(x) = \frac{|f(x)|}{-\exp\left(\left(\frac{df}{dx}(x)\right)^2 + 1\right)}$$

where lower is better. This function is just an educated guess, but it has to have some properties, as the derivative of  $f$  tends to 0,  $\sigma(x)$  should diverge to infinity.

$$\lim_{\frac{df}{dx} \rightarrow 0} \sigma(x) = \infty$$

If  $f(x) = 0$  we found an actual root in the first guess meaning that  $\sigma(x)$  should be 0. Formula 4.3 doesn't satisfy this property since it's undefined if  $f'(x) = 0$  and  $f(x) = 0$ , but we can extend it's definition such that

$$\sigma(x) = \begin{cases} \frac{|f(x)|}{-\exp\left(\left(\frac{df}{dx}(x)\right)^2 + 1\right)} & f(x) \neq 0 \text{ and } \frac{df}{dx} \neq 0 \\ 0 & \text{else} \end{cases}$$

Figure 4.3.: Logarithmic heat diagram of  $\sigma(x)$ , darker/bluer is better

As we can see in figure 4.3 where darker/bluer values are better than yellow/red areas that  $\sigma(x)$  indeed has all of the desired properties.

After we rated all of the 1000 guesses we can pick the best one as a first guess and use the modified Newtons method with it. We do this process 256 times by default. In theory we could therefor use the WKB approximation for potentials with up to 256 turning points.

```

1 fn find_zeros(phase: &Phase, view: (f64, f64)) -> Vec<f64> {
2     let phase_clone = phase.clone();
3     let validity_func = Arc::new(move |x: f64| {
4         1.0 / (2.0 * phase_clone.mass).sqrt() * derivative(&|t| (phase_clone.
5             potential)(t), x).abs()
6         - ((phase_clone.potential)(x) - phase_clone.energy).pow(2)
7     });
8     let mut zeros = NewtonsMethodFindNewZero::new(validity_func, ACCURACY, 1e4 as
9         usize);
10    (0..MAX_TURNING_POINTS).into_iter().for_each(|_| {
11        let modified_func = |x| zeros.modified_func(x);
12        let guess = make_guess(&modified_func, view, 1000);
13        guess.map(|g| zeros.next_zero(g));
14    });
15    let view = if view.0 < view.1 {
16        view
17    } else {
18        (view.1, view.0)
19    };
20    let unique_zeros = zeros
21        .get_previous_zeros()
22        .iter()
23        .filter(|x| **x > view.0 && **x < view.1)
24        .map(|x| *x)
25        .collect::<Vec<f64>>();
26    return unique_zeros;
27 }
28 }

```

Here `make_guess` uses  $\sigma(x)$  and returns the best guess. `NewtonsMethodFindNewZero` is the modified version of Newtons method where all the roots are stored and its implementation of `Func<f64, f64>` is just defined as

$$\frac{f(x)}{\prod_{r \in Z} (x - r)} \quad (4.14)$$

Where the set  $Z$  is the set of all the zeros that have been found previously. After the 256 iterations we filter out all the zeros that aren't in the view. Equation 4.14 is implemented in `NewtonsMethodFindNewZero`. Unfortunately this procedure can't be implemented asynchronously since you have to know all previous zeros before you can find a new one.

Once we found the zeros we need to group them as previously mentioned the derivative of the validity function (4.13) must be positive if the boundary point is on the left and negative when its on the right side of the turning point. It could be the case that if the turning point is in the view that one of the boundary points is actually outside the view. For this we can use Regula falsi combined with bisection. We will do this for both the left and right most turning point if there was only one boundary found.

## 4.4. Wave Function Parts

All the equations of the WKB approximation split into multiple parts. This is also reflected in the program architecture. The trait `WaveFunctionPart` represents one of these sections.

```
1 pub trait WaveFunctionPart: Func<f64, Complex64> + Sync + Send {  
2     fn range(&self) -> (f64, f64);  
3     fn as_func(&self) -> Box<dyn Func<f64, Complex64>>;  
4 }
```

These parts all need to implement the `Func<_>` trait and are only valid in the range returned by `WaveFunctionPart::range`.

As previously mentioned the architecture has originally been designed around the assumption that both turning points will be used in the oscillating region. Because of this there is a specialization of this structs that can work with so called “operations”. Operations were used to make the transition between the two parts of the osculating regions smoother. An operation is just a function  $f : \mathbb{C} \rightarrow \mathbb{C}$  that will be applied over the whole function. The author decided not to change the architecture to the new method because the program could in theory be extended further. The wave function parts that support operations implement the `WaveFunctionPartWithOp` trait.

### 4.4.1. ApproxPart

An `ApproxPart` is the function around a turning point. This includes the Airy, oscillating WKB and exponential WKB part. At the same time it also handles the joints between the Airy and WKB functions.

Two joints are constructed and they have the highest “priority” when evaluating an `ApproxPart` for a given  $x$ .

```
1 fn eval(&self, x: f64) -> Complex64 {  
2     if is_in_range(self.airy_join_l.range(), x) && ENABLE_AIRY_JOINTS {  
3         return self.airy_join_l.eval(x);  
4     } else if is_in_range(self.airy_join_r.range(), x) && ENABLE_AIRY_JOINTS {  
5         return self.airy_join_r.eval(x);  
6     } else if is_in_range(self.airy.ts, x) {  
7         return self.airy.eval(x);  
8     } else {  
9         return self.wkb.eval(x);  
10    }  
11 }
```

The term “priority” is used to say how far up the if statement the function is. Or in other words, functions with a higher priority are preferred. Because the joints overlap with both the ranges of the Airy and WKB function is important that they are given a higher priority. Further on the range of the Airy part is also included in the WKB range because of this the WKB part has the least priority.

As we can see, the check if the joints are even enabled happens here. Because `ENABLE_AIRY_JOINTS` is a constant. The compiler will remove the branches that are always false automatically

(see Appendix A.2). This means that in theory the program should run a little faster if `ENABLE_AIRY_JOINTS` is disabled. This has to be taken into account when benchmarking.

#### 4.4.2. PureWkb

In the case that there are no turning points or none were found. The program will still try to calculate a wave function. This is done by taking `APPROX_INF` as the turning points. This can be done because no Airy functions will be used. In this case the turning points just act as a bound of integration.

From experience the results are inaccurate but still usable. At least in the case where the turning points were missed by Newtons method the WKB parts were fairly accurate, but unsurprisingly diverged at the turning points because there were no Airy functions.

The struct `PureWkb` works the same as `ApproxPart` but only implements the WKB functions. It does not contain any Airy functions or joints.

### 4.5. Wave Function

To combine all the `WaveFunctionPart` structs, we will define the `WaveFunction` struct. Under the hood it will also calculate all the variables and construct all the `WaveFunctionPart` structs.

First we need to calculate the energy for the given parameters that are passed to the constructor. Note the this energy will also be printed to the terminal.

```
1 let energy = energy::nth_energy(n_energy, mass, &potential, approx_inf);
2 println!("{}", Energy::{:9}, Ordinal(n_energy).to_string(), energy);
```

Using the energy we can calculate the view as described in section 4.3.

```
1 (
2     lower_bound * (upper_bound - lower_bound) * view_factor,
3     upper_bound * (upper_bound - lower_bound) * view_factor,
4 )
```

Once we've got the view, we can calculate all the turning points and there Airy functions along with them, using `AiryWaveFunction::new()`. In the case that there are turning points we can then go through each turning point and also copy it's neighbors. For the outer most turning points we will take `approx_inf` as its neighbor.

With these groups of 3 we can construct a `WkbWaveFunction` for each of the turning points. However there were issues when dividing the oscillating part of the wave function was split into two parts with different turning points. As previously mentioned according to Hall (2013) it should be mathematically indistinguishable when using either of the turning points, but there arise discontinuities at the transition region. Because of that it has been decided that only the left turning point will be used.

Unfortunately in this method even though the function is continuous it will not be symmetric about the mid point of the oscillating region. This has the effect that the probabilities will be lower on the right none the less they should have the same probability. Because of the architecture of the program the oscillating part will still be split into two distinct regions.

While iterating over the turning points we can also calculate the ranges in which the functions are valid.

Once we have all the `WkbWaveFunction` instances we need to group them with the `AiryWaveFunction` instances. Using those pairs we can finally construct all the `ApproxPart` instances.

Finally we need to apply the scaling which may be one of the following options (where  $a \in \mathbb{C}$ ):

**None** The solution wont be multiplied by anything.

**Mul(a)** The solution will be multiplied by  $a$ .

**Renormalize(a)**  $\Psi(x)$  will be renormalized such that  $\int_{-\infty}^{\infty} |a\Psi(x)|^2 dx = 1$ . This can be useful to add a phase to the wave function.

In the case that no turning points are found WKB will be inaccurate. But for completeness we will assume that `approx_inf` is a turning point. Then we can insert two `WkbWaveFunction` instances without the Airy functions. This behavior is implemented in `PureWkb`. Afterwards we apply the same scaling procedure (4.5) as if there were turning points.

In this case you'll also get a warning in the terminal that no turning points were found. Because the results can be inaccurate.

#### 4.5.1. Super Position

Because the super position principal is also applicable to energies it is possible that  $\Psi(x)$  is a sum of wave functions with different energies.

On the implementation side this means that we can create a struct `SuperPosition` that is constructed with a list of energy levels and `ScalingType` that can be used to construct the previously discussed `WaveFunction`. Its implementation of `Func<f64, Complex64>` will then sum over all the results of the individual `WaveFunction` structs.

## 5. Program Manual

In the `src` directory you will find the `main.rs` file. After the imports (lines with `use`) you can find all the constants that can be configured. In the description below, (E) stands for “expert” and means that you should use the default unless you really know what you’re doing.

### Concurrency Configurations Tune accuracy and performance

**INTEG\_STEPS** The number of steps that will be used to integrate over an interval

**TRAPEZE\_PER\_THREAD (E)** The number of trapezes that are calculated on a thread in sequence. This number must be smaller than `INTEG_STEPS`.

**NUMBER\_OF\_POINTS** The number of points that will be written to the output file.

**APPROX\_INF** These are the values for “ $\pm\infty$ ”. Where the first number is  $-\infty$  and the second number is  $\infty$ . Most importantly outside of this interval  $V(x) > E$ .

### Visual Configurations Adjust the width of joints

**VIEW\_FACTOR** This factor is used in 4.3 as  $f_{view}$ . It determines in which range the output will be calculated. This depends heavily on the potential and the energy and you probably will have to change it. If the wave function is too small and most of the plot is close to 0 then this factor has to be lowered. If the wave function is not nearly 0 at the boundary of the view, this factor should be increased. Note this factor does not influence the calculation itself.

**ENABLE\_WKB\_JOINTS** If set to `true` joints will be added between Airy and WKB wave function parts. If set to `false` no joints will be added at this boundary.

**AIRY\_TRANSITION\_FRACTION (E)** When a joint between an Airy and a WKB function has to be added, we have to know how wide the joint should be. The width is calculated by taking the distance between the turning point boundaries and multiplying it by this number.

**VALIDITY\_LL\_FACTOR (E)** This factor gets used as  $a$  in 4.13. Higher values will create larger ranges for Airy functions.

### 5.1. WaveFunction

When you only have one energy level you should use `WaveFunction::new`.

```
1 let wave_function = wave_function_builder::WaveFunction::new(  
2     & /*potential*/,
```

```

3      /*mass*/,
4      /*nth energy*/,
5      APPROX_INF,
6      1.5,
7      ScalingType::/*Scaling*/,
8  );

```

The example above has to be placed right after the `fn main()` line. You have to replace all the commentaries (`/*...*/`) with the values you want. For the first you can choose a potential from section 5.4 for this you can type `potentials::/*potential*/`.

For the Mass you can just use a normal float.

“nth energy ” must be a positive integer (including 0) and is the nth energy level of the potential.

And as for the scaling type, choose one of the options described at the end of section ??.

## 5.2. SuperPosition

To construct a super position you can add this to your main function

```

1  let wave_function = wave_function_builder::SuperPosition::new(
2      &/*potential*/,
3      /*mass*/,
4      &[
5          (/*nth energy*/, /*phase*/),
6          (/*nth energy*/, /*phase*/),
7          // ...
8      ],
9      APPROX_INF,
10     1.5, // view factor
11     ScalingType::/*scaling*/),
12 );

```

Just like in section 5.1 you have to replace all the commentaries (`/*...*/`) with the values you want.

“potential” you have to choose a potential from section 5.4.

“mass” your mass as a float.

“nth energy ” must be a positive integer (including 0) and is the nth energy level of the potential.

“phase” a complex number that the wave function with the corresponding energy will be multiplied by. To make a complex number you can use `complex(/*Re*/, /*Im*/)`.

“// ...” you can add as many energies as your computer can handle.

And as for the scaling type, choose one of the options described at the end of section ??.

## 5.3. Plotting

For all the plotting methods mentioned below you’ll need an output directory in which the files will be placed.

```
1 let output_dir = Path::new("output");
```

The default is *output*, you can choose any directory name that you'd like. The folder will be located where you ran the program. The data calculated by the program will be stored as space separated values like in the example below (the first line will not be in the output file).

```
x    Re    Im
1.0  2.718  3.141
2.0  1.414  1.465
```

Every line is a data point where the first number is the x-coordinate, the second the real part of  $\Psi(x)$  and the third the imaginary part of  $\Psi(x)$

### 5.3.1. WaveFunction

For a WaveFunction as we've seen in section 5.1 you have three options.

#### **plot\_wavefunction**

With `plot::plot_wavefunction` the result will be plotted as one function in gnuplot.

```
1 plot::plot_wavefunction(&wave_function, output_dir, "data.txt");
```

You can replace *data.txt* with another file name.

`plot_wavefunction_parts`

`plot_probability`

## 5.4. Potentials

**square** Normal square potential as used in Hall (2013).

$$x^2$$

**mexican\_hat** 4th degree polynomial that looks like a mexican hat, with 2 minima.

$$(x-4)^2(x+4)^2$$

**double\_mexican\_hat** 6th degree polynomial that has 3 minima.

$$(x-4)^2x^2(x+4)^2$$

**triple\_mexican\_hat** 8th degree polynomial that has 4 minima.

$$(x-6)^2(x-3)^2(x+3)^2(x+6)^2$$

**smooth\_step** Step function that goes to `ENERGY_INF` outside the interval  $(-5, 5)$ . Joints were added at  $\pm 5$  to make the function differentiable.

#### 5.4.1. Custom Potentials

To create a custom potential you'll have to define a function like shown below.

```
1 fn my_potential(x: f64) -> f64 {  
2     return /*some calculation*/;  
3 }
```

`my_potential` is the name that you can choose and have to use later when you're passing it to `WaveFunction::new`. `/*some calculation*/` can be any Rust code that results in a `f64`.

#### Examples

Negative bell curve  $(-e^{-x^2} + 1)$

```
1 fn neg_bell(x: f64) -> f64 {  
2     return -(-x.powi(2)).exp();  
3 }
```

General polynomial (might not work for all configurations)

```
1 const COEFFICIENTS: [f64;4] = [a, b, c, d]  
2 fn polynomial(x: f64) -> f64 {
```

```
3   let mut result = 0.0;
4   for n in 0..COEFFICIENTS.len() {
5       result += x.powi(n) * COEFFICIENTS[n];
6   }
7   return result;
8 }
```

You need to set values for a, b, etc. and they need to be floating point numbers or you'll get error E0308. For example 1 would cause an error but 1.0 or 3.141 are correct. You can add even more coefficients if you'd like. The 4 in the square brackets is the degree of the polynomial plus 1. The potential above would mathematically be  $a + bx + cx^2 + dx^3$ .

## A. Detailed Calculations and Tests

### A.1. Proofs

#### A.1.1. Smoothness of Transitionfunction

Given that

$$f : \mathbb{R} \rightarrow \mathbb{C} \quad (\text{A.1})$$

$$g : \mathbb{R} \rightarrow \mathbb{C} \quad (\text{A.2})$$

$$\{f, g\} \in C^1 \quad (\text{A.3})$$

$$\{\alpha, \delta\} \in \mathbb{C} \quad (\text{A.4})$$

define (Hall, 2013)

$$\chi(x) = \sin^2\left(\frac{\pi(x - \alpha)}{2\delta}\right) \quad (\text{A.5})$$

$$(f \sqcup g)(x) = f(x) + (g(x) - f(x))\chi(x) \quad (\text{A.6})$$

and proof that

$$\frac{d(f \sqcup g)}{dx}(\alpha) = \frac{df}{dx}(\alpha) \quad (\text{A.7})$$

$$\frac{d(f \sqcup g)}{dx}(\alpha + \delta) = \frac{dg}{dx}(\alpha + \delta). \quad (\text{A.8})$$

Calculate derivatives

$$\frac{d\chi}{dx}(x) = \frac{\pi}{2\delta} \sin\left(\frac{\pi(x - \alpha)}{\delta}\right) \quad (\text{A.9})$$

$$\frac{d(f \sqcup g)}{dx}(x) = \frac{df}{dx}(x) + \left(\frac{dg}{dx}(x) - \frac{df}{dx}(x)\right)\chi(x) + (g(x) - f(x))\frac{d\chi}{dx}(x). \quad (\text{A.10})$$

Note that

$$\frac{d\chi}{dx}(\alpha) = 0 \quad (\text{A.11})$$

$$\chi(\alpha) = 0 \quad (\text{A.12})$$

$$\frac{d\chi}{dx}(\alpha + \delta) = 0 \quad (\text{A.13})$$

$$\chi(\alpha + \delta) = 1 \quad (\text{A.14})$$

therefor

$$\frac{d(f \sqcup g)}{dx}(\alpha) = \frac{df}{dx}(\alpha) + 0 \left( \frac{dg}{dx}(\alpha) - \frac{df}{dx}(\alpha) \right) + 0(g(x) - f(x)) = \frac{df}{dx}(\alpha) \quad (\text{A.15})$$

and

$$\frac{d(f \sqcup g)}{dx}(\alpha + \delta) = \frac{df}{dx}(\alpha + \delta) + 1 \left( \frac{dg}{dx}(\alpha + \delta) - \frac{df}{dx}(\alpha + \delta) \right) + 0(g(x) - f(x)) \quad (\text{A.16})$$

$$\frac{d(f \sqcup g)}{dx}(\alpha + \delta) = \frac{df}{dx}(\alpha + \delta) + \frac{dg}{dx}(\alpha + \delta) - \frac{df}{dx}(\alpha + \delta) = \frac{dg}{dx}(\alpha + \delta) \blacksquare. \quad (\text{A.17})$$

## A.2. Branch Elimination

To check if branches with a constant condition of `false` gets removed we will use “Compiler Explorer” on <https://godbolt.org/>. This is an online tool to generate the assembly of source code. The settings used for this test are “Rust” for the language, “rustc 1.65.0” for the compiler with flags “-O”.

### Rust Code

```
const COND: bool = true;

pub fn test(x: f64) -> f64 {
    if x > 5.0 && COND {
        return x % 5.0;
    } else {
        return x*x;
    }
}
```

### Assembly

```
.LCPI0_0:
    .quad    0x4014000000000000
example::test:
    push     rax
    ucomisd  xmm0, qword ptr [rip + .
        LCPI0_0]
    jbe      .LBB0_1
    movsd    xmm1, qword ptr [rip + .
        LCPI0_0]
    call     qword ptr [rip +
        fmod@GOTPCREL]
    pop      rax
    ret
.LBB0_1:
    mulsd    xmm0, xmm0
    pop      rax
    ret
```

As we can see in the `true` case the `.LBB0_1` label was inserted which means the code will branch.

### Rust Code

```
const COND: bool = false;

pub fn test(x: f64) -> f64 {
    if x > 5.0 && COND {
```

### Assembly

```
example::test:
    mulsd    xmm0, xmm0
    ret
```

```
        return x % 5.0;
    } else {
        return x*x;
    }
}
```

In the `false` case the compiler directly calculates  $x^2$  directly without any checks since the first condition is always `false`.
