Vorwort

Der Rest der Arbeit wird in Englisch sein aber ich habe mich entschieden eine kleine Zusammenfassung zu schreiben, so dass jeder zumindest die Grundlagen meiner Arbeit versteht. Zu begin des 20. Jahrhunderts gab es einen Umschwung in der Physik, Quanten Mechanik wurde entdeckt. Diese neue Theorie kann nicht mehr präzise voraussagen machen wie es zuvor der Fall war. Man kann nur noch sagen mit welcher Wahrscheinlichkeit etwas passiert und ein Partikel kann an zwei Orten gleichzeitig sein.

Vielleicht haben Sie schon einmal von Schrödingers Katze gehört. Dies war ein Gedankenexperiment von Schrödinger um auf zu zeigen wie absurd seine Theorie wirklich ist und dass sie nicht stimmen könne. Stell dir vor du schliesst deine Katze in eine Box ein. In dieser Box ist ein Atom das entweder zerfallen kann oder nicht. Dazu gibt es einen Detektor der misst ob das Atom zerfallen ist, in diesem Fall wird ein Gift frei gelassen und die Katze stirbt. Das Problem ist jetzt aber, dass dieses Atom den Regeln der Quanten Mechanik folgt und deshalb gleichzeitig bereits zerfallen ist und nicht zerfallen ist, die einzig logische Schlussfolgerung ist deshalb, dass die Katze gleichzeitig Tod und am leben ist (Schrödinger, 1935).

In der Realität funktioniert es wahrscheinlich jedoch nicht so. Heisst das Universum "entscheidet" ob die Katze gestorben ist oder nicht, jedoch weiss man bis Heute nicht wann das Universum "entscheidet".

Damit die Katze gleichzeitig Tod und Lebendig sein kann brauchen wir die Wellenfunktion. Sie beschreibt alles was in unserem Universum gerade passiert und "speichert" wie wahrscheinlich es ist, dass die Katze tot ist.

In meiner Maturaarbeit habe ich ein Programm geschrieben das genau diese Wellenfunktion ausrechnet in einem sehr vereinfachten Universum. Weil ich schon lange mal wissen möchte wie genau dieses bizarre Objekt aussieht. Auf der Titel Seite ist eine dieser Wellenfunktionen abgebildet.

1. Introduction

Richard Feynmann one of the core people behind our modern theory of quantum mechanics repeatedly said: "I think I can safely say that nobody understands quantum mechanics.". Nothing behaves like in our every day lives. Everything is just a probability and nothing certain. Even Schrödinger the inventor of the equation that governs all of those weird phenomena rejected the idea that there are just probabilities.

In this paper we will try to understand this world a little bit better by looking at wave functions in a simplified universe. This universe only has 1 dimension and there will not be any sense of time. This means we will be able to actually see how the wave function looks like in a graph.

1.1. Goals

The goal of this Maturaarbeit is to write a program, schroeding-approx that calculates solutions to the time independent Schrödinger equation in 1 dimension for a large verity of potentials. We assume that the wave function, $\Psi(x)$ will converges to 0 as x goes to $\pm \infty$.

2. Preliminary

2.1. Schrödinger Equation

In 1926 Erwin Schrödinger changed our understanding of quantum physics with the Schrödinger equation. Based on the observations of de Broglie that particles behave like waves he developed a wave equation which describes how the waves move and change in a given potential V(x) or Hamiltonian \hat{H} .

$$i\hbar \frac{\partial}{\partial t} \Psi(x,t) = \left[-\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + V(x,t) \right] \Psi(x,t)$$

Or more general

$$\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi(x,t) = \hat{H}\Psi(x,t)$$

The time independent version that is going to be used later, ignores the change over time and is much simpler to solve since it is *only* an ordinary differential equation instead of a partial differential equation.

$$E\psi(x) = \hat{H}\psi(x)$$

or

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2}(x) + V(x)\psi(x) = E\psi(x)$$

Even with the time independent equation it is very difficult to get analytical solutions, because of this there are mainly three approaches to approximate solutions of $\psi(x)$, perturbation theory, density functional field theory and WKB approximation. Perturbation theory's goal is to give an analytical approximation which means it is extremely difficult to implement for a computer. WKB on the other hand is much better since it is to some degree a step by step manual.

2.2. Rust

Rust is one of the newer programming languages and attempts to replace C/C++ which are notoriously difficult to work with. It supports both functional and object-oriented paradigms. It is much safer in terms of memory and promises the same performance as C. One of the goals of Rust is fearless concurrency which means everybody should be able to write concurrent

code without deadlocks and data races. This means calculations can utilize the full potential of the CPU without countless hours of debugging.

Functional programming languages are especially useful for mathematical problems, because they are based on the same mathematics as the problem.

Rust as of the time of writing this document is not yet standardized meaning the code provided might no longer be correct with one of the newer Rust versions.

In case you aren't familiar with Rust, it has excellent documentation on https://doc.rust-lang.org/book/.

2.3. Interpretation of Quantum Mechanics

The author believes in the many worlds interpretation of Hugh Everett. "The wave interpretation. This is the position proposed in the present thesis, in which the wave function itself is held to be the fundamental entity, obeying at all times a deterministic wave equation." (DeWitt und Graham, 2015, p. 115). This means that the observer is also quantum mechanical and gets entangled with one particular state of the system that is being measured (DeWitt und Graham, 2015, p. 116). This is some what different to the popular explanation of many worlds but has the same results and is, at least to the author more reasonable.

An important point for the author also was that the theory accepts quantum mechanics as it is and doesn't make unreasonable assumption such as that the observer plays an important role.

On top of that this interpretation also discards the need for an "observation" in the program which would also be mathematically impossible (DeWitt und Graham, 2015, p. 111).

2.4. Complex Numbers

In quantum mechanics it's customary to work with complex numbers. Complex numbers are an extension to the real numbers, since Rust will do most of the heavy lifting here are the most important things that you should know

$$i^{2} = -1$$

$$z = a + bi$$

$$Re(z) = a$$

$$Im(z) = b$$

$$\overline{z} = a - bi$$

$$||z||^{2} = a^{2} + b^{2}$$

$$e^{\theta i} = \cos(\theta) + i\sin(\theta)$$

i is the imaginary unit, z is the general form of a complex number where $\{a,b\} \in \mathbb{R}$, \overline{z} is the complex conjugate and $||z||^2$ is the norm square of z. The last equation is the Euler's formula, it rotates a number in the complex plane by θ radians.

The complex plane is similar to the real number line, every complex number can be represented on this plane where Re(z) is the x-coordinate and Im(z) is the y-coordinate.

2.5. Gnuplot

Gnuplot is a cross platform plotting program that is very simple to use. schroedingerapprox will output a file data.txt, you can plot the function by typing gnuplot and then typing

1 call "plot.gnuplot"

to plot the real part of the wave function, or

1 call "plot 3d.gnuplot"

to see the full complex wave function.

If you'd like to learn more about Gnuplot you can read there user manual on http://www.gnuplot.info/

2.6. Planck Units

By using Planck units the equations get a little bit easier. Working in Planck units means that all fundamental constants are equal to 1.

$$c = k_B = G = \hbar = 1.$$

This means that the constants will usually cancel out.

To convert to SI units we can just multiply powers of the constants such that there unit results in one of the base units.

$$l_{\rm Planck} = l_{\rm SI} \sqrt{\frac{G\hbar}{c^3}} \qquad 1 \text{ m}_{\rm Planck} \approx 1.616255(18) \cdot 10^{-35} \text{ m} \qquad \text{(CODATA, 2022a)}$$

$$m_{\rm Planck} = m_{\rm SI} \sqrt{\frac{c\hbar}{G}} \qquad 1 \text{ kg}_{\rm Planck} \approx 2.176434(24) \cdot 10^{-8} \text{ kg} \qquad \text{(CODATA, 2022b)}$$

$$t_{\rm Planck} = t_{\rm SI} \sqrt{\frac{G\hbar}{c^5}} \qquad 1 \text{ s}_{\rm Planck} \approx 5.391247(60) \cdot 10^{-44} \text{ s} \qquad \text{(CODATA, 2022c)}$$

(Gaarder Haug, 2016, Table 1)

The program will take all of its in- and outputs in Planck units.

3. Methods

3.1. Program Architecture

The program has multiple interfaces or traits as they are called in Rust that give the program some abstraction.

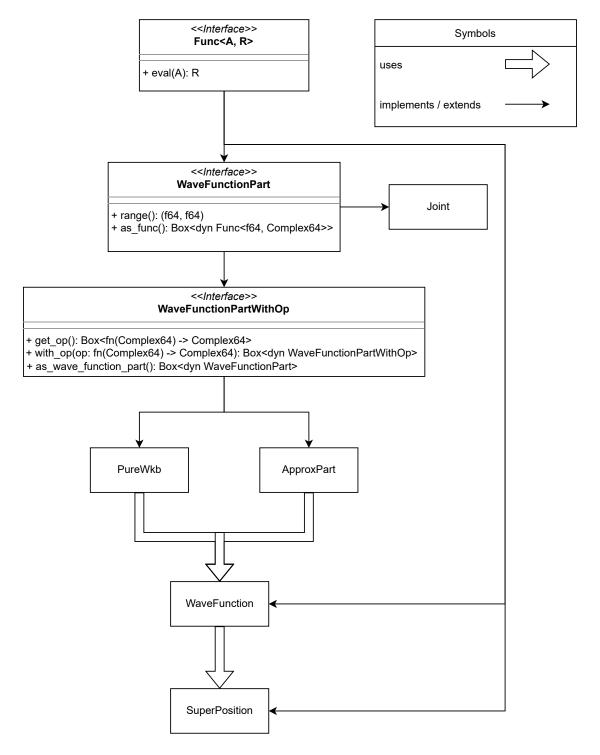

Figure 3.1.: UML diagram of program architecture

Since current version of Rust does not support manual implementations of std::ops::

Fn we have to define our own trait for functions Func<A, R> where A is the type of the argument and R is the return type. Later we will use this trait to implement functions for integration, evaluation and more useful utilities.

WaveFunction is at the heart of the program, it contains all the functionality to build wave functions. It is composed of WaveFunctionPart which represent either a Joint, PureWkb or an ApproxPart. With the range function we can check when they are valid.

3.2. Newtons Method

Newton's method, also called the Newton-Raphson method, is a root-finding algorithm that uses the first few terms of the Taylor series of a function f(x) in the vicinity of a suspected root (Weisstein, 2022). It makes a sequence of approximations of a root x_n that in certain cases converges to the exact value where

$$\lim_{n\to\infty} f(x_n) = 0$$

The sequence is defined as

$$x_0 = a$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

Visually this looks like figure 3.2 f(x) = (x-2)(x-1)(x+1).

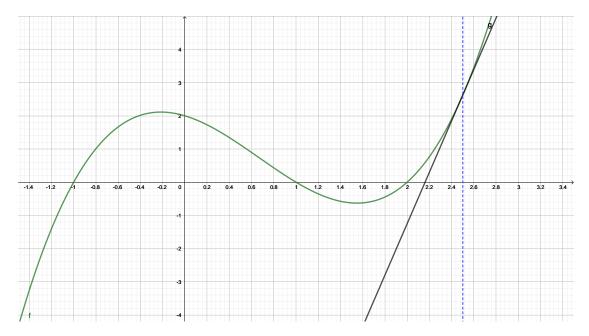

Figure 3.2.: Illustration of Newtons method, f(x) = (x-1)(x-2)(x+1).

The blue line indicates the initial guess which in this case is 2.5 the black line (g(x)) is a tangent to f(x) at (guess, f(guess)) the next guess will be where the tangent intersects the x-Axis (solution of g(x) = 0). This will converge rather quickly compared to other methods such as Regula falsi.

```
1
    pub fn newtons method<F>(f: &F, mut guess: f64, precision: f64) -> f64
 2
 3
             F: Fn(f64) -> f64,
 4
 5
        loop {
 6
             let step = f(guess) / derivative(f, guess);
 7
             if step.abs() < precision {</pre>
 8
                 return guess;
 9
             } else {
                 guess -= step;
10
11
             }
12
        }
13
    }
```

In Rust the sequence is implemented with a function that takes a closure f, the initial guess guess and a stop condition precision the function will return if $||cfracf(x_n)f'(x_n)||$ is less than precision.

From the structure of the algorithm it is very tempting to implement it recursively, but by using a loop it is much faster since there are no unnecessary jumps and the precision can (at least in theory) be 0 without causing a stack overflow.

3.3. Regula Falsi with Bisection

Newtons method fails if the first guess is at a maximum, since the step would go to infinity. For this case we can first use a bisection search to detect a sign change. We need to do a bisection search since Regula falsi requires two guesses.

The algorithm itself is quite simple. To start we need

$$f(x): \mathbb{R} \to \mathbb{R} \tag{3.1}$$

$$\{a \in \mathbb{R} \mid f(a) \le 0\} \tag{3.2}$$

$$\{b \in \mathbb{R} \mid f(b) \ge 0\}. \tag{3.3}$$

Then we can draw a line between the two points (a, f(a)) and (b, f(b)). Then a becomes the x-value where the line intersects the x-axis becomes the new b, when we do the process again with the new b we will get our new value for a. We can repeat this process until we cross a fresh hold for the accuracy and the result will be the last intersection of the line with the x-axis.

3.4. Derivatives

Derivatives can be calculated numerically as in the C++ library Boost (John Maddock, 2022). The author implemented a analytical system for derivatives in Go. From that experience the benefit is negligible compared to the increase in performance and in development time since every function is a special object.

```
1
    pub fn derivative<F, R>(func: &F, x: f64) -> R
 2
 3
        F: Fn(f64) \rightarrow R + ?Sized,
 4
        R: Sub<R, Output = R> + Div<f64, Output = R> + Mul<f64, Output = R> + Add<R,
             Output = R>,
 5
    {
 6
        let dx = f64::epsilon().sqrt();
 7
        let dx1 = dx;
 8
        let dx2 = dx1 * 2.0;
 9
        let dx3 = dx1 * 3.0;
10
        let m1 = (func(x + dx1) - func(x - dx1)) / 2.0;
11
12
        let m2 = (func(x + dx2) - func(x - dx2)) / 4.0;
13
        let m3 = (func(x + dx3) - func(x - dx3)) / 6.0;
14
15
        let fifteen m1 = m1 * 15.0;
16
        let six m2 = m2 * 6.0;
17
        let ten dx1 = dx1 * 10.0;
18
19
        return ((fifteen m1 - six m2) + m3) / ten dx1;
20
```

f64::epsilon().sqrt() is approximately 0.000000014901161. f64::epsilon() is the smallest double precision floating point number where $1 + \epsilon \neq 1$. this has been chosen for dx because it should be fairly precise.

3.5. Integration

The same principles apply to integrals as to derivative it would not be a great benefit to implement an analytic integration system. Integrals would also be much more difficult to implement than derivatives since integrals can not be broken down in to many smaller integrals that can be computed easily instead it needs to be solved as is.

One approach would be to use the same method as with the derivative, take the definition with the limit and use a small value but this method can be improved in this case, since integrals calculate areas under curves a trapeze is more efficient and accurate then the rectangle that results from the definition.

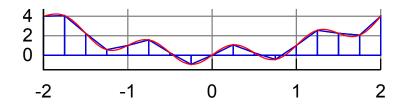

Figure 3.3.: Illustration of integration with trapeze from Wkipedia (2022).

Figure 3.3 shows visually how the methods work, each blue trapeze from start (*a*) to end (*b*) has an area of

$$\int_{a}^{b} f(x) dx \approx (b-a) f\left(\frac{a+b}{2}\right).$$

One trapeze would be fairly inaccurate to calculate the area under the function but as the area from *a* to *b* is subdivided further the result become better and better.

The general structure of the algorithm can very easily be run in parallel since it doesn't matter in which order the segments are added together and the segments also don't dependent on one another. In Rust this is implemented using rayon. Rayon is an implementation for parallel iterators meaning that normal data structures that implement std::iter can be run in parallel <code>just</code> by changing ::iter() to ::par_iter(). This might not work in all cases because of memory safety but in this case the borrow checker will throw an error and the code wont compile.

```
pub trait ReToC: Sync {
    fn eval(&self, x: &f64) -> Complex64;
}

pub struct Point {
    pub x: f64,
    pub y: Complex64,
}
```

These functions were implemented very early and need some refractory. Such that functions with states, like wave functions that store parameters, can be integrated there is a trait ReToC. ReToC describes a function $f : \mathbb{R} \to \mathbb{C}$ (Fn(f64) -> Complex64).

Point stores both the input (x) and the output (y) of a function.

```
pub fn evaluate function between(f: &dyn ReToC, a: f64, b: f64, n: usize) -> Vec<</pre>
        Point> {
 2
        if a == b {
 3
             return vec![];
 4
        }
 5
 6
        (0..n)
 7
             .into par iter()
 8
             .map(|i| index_to_range(i as f64, 0.0, n as f64 - 1.0, a, b))
 9
             .map(|x| Point { x, y: f.eval(&x) })
10
             .collect()
11
```

ReToC can be passed to evaluate_function_between it calculates n points between an interval from a to b and returns a vector of Point.

```
1
    pub fn trapezoidal approx(start: &Point, end: &Point) -> Complex64 {
 2
        return complex(end.x - start.x, 0.0) * (start.y + end.y) / complex(2.0, 0.0);
 3
    }
 4
    pub fn index to range(x: f64, in min: f64, in max: f64, out min: f64, out max: f64)
 5
 6
        return (x - in_min) * (out_max - out_min) / (in_max - in_min) + out_min;
 7
 8
 9
    pub fn integrate(points: Vec<Point>, batch_size: usize) -> Complex64 {
10
        if points.len() < 2 {</pre>
11
            return complex(0.0, 0.0);
12
13
14
        let batches: Vec<&[Point]> = points.chunks(batch size).collect();
15
16
        let parallel: Complex64 = batches
17
            .par_iter()
18
            .map(|batch| {
19
                let mut sum = complex(0.0, 0.0);
20
                for i in 0..(batch.len() - 1) {
21
                    sum += trapezoidal_approx(&batch[i], &batch[i + 1]);
22
23
                return sum;
24
            })
25
            .sum();
26
27
        let mut rest = complex(0.0, 0.0);
28
29
        for i in 0..batches.len() - 1 {
30
            rest += trapezoidal_approx(&batches[i][batches[i].len() - 1], &batches[i +
                1][0]);
31
32
33
        return parallel + rest;
34
```

The actual integration happens in integrate, it calculates the areas of the trapezes between the points passed to it. For optimization 1000 trapezes are calculated per thread because it would take more time to create a new thread then to actually do the calculation, this has to be further investigated and 1000 might not be optimal. The calculations performed per thread are called a batch, after all batches have been calculated the boundaries between batches also has to be considered therefor they are added in the end with rest

3.6. Transition Regions

The approximation that will be used splits $\Psi(x)$ into multiple parts that do not match perfectly together.

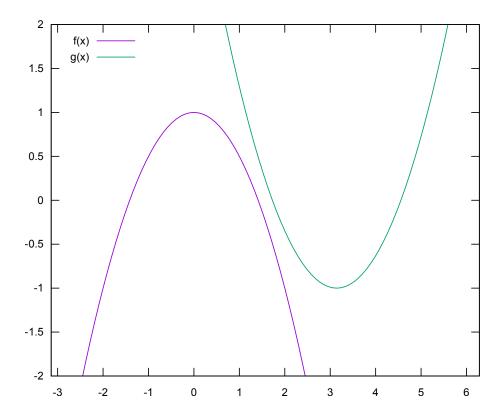

Figure 3.4.: Example for joining functions

Lets consider an example, in figure 3.6 we can see two Taylor series of cosine. Now we have to join the two functions at $x = \pi/2$ such that its a mathematically smooth transition.

$$f(x) = 1 - \frac{x^2}{2} \tag{3.4}$$

$$f(x) = 1 - \frac{x^2}{2}$$

$$g(x) = \frac{(x - \pi)^2}{2} - 1$$
(3.4)

As a first guess lets join f(x) and g(x) with a step function, this means that the joint function h(x) will be

$$h(x) = \begin{cases} f(x) & x < \frac{\pi}{2} \\ g(x) & x > \frac{\pi}{2} \end{cases}.$$

This gives us 3.6 which is obviously not smooth.

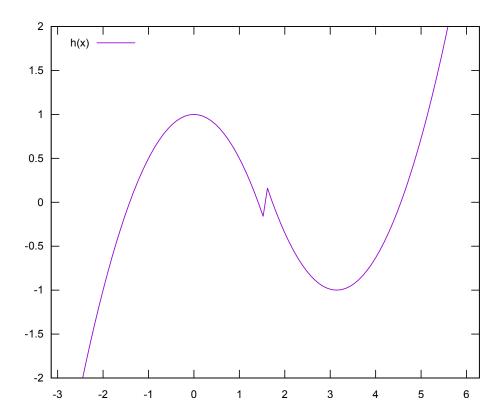

Figure 3.5.: Plot of h(x) with step joint

If we use the formula from (Hall, 2013, p. 325, section 15.6.4) with

$$\delta = 0.5$$

$$\alpha = \frac{\pi}{2} - \frac{\delta}{2}$$

$$\chi(x) = \sin^2\left(x\frac{\pi}{2}\right)$$

this results in

$$h(x) = \begin{cases} f(x) & x < \alpha \\ g(x) & x > \alpha + \delta \end{cases}$$
$$f(x) + (g(x) - f(x))\chi(\frac{x - \alpha}{\delta}) \quad else$$

which is mathematically smooth as we can see in figure 3.6 (proof in Appendix A.1.1).

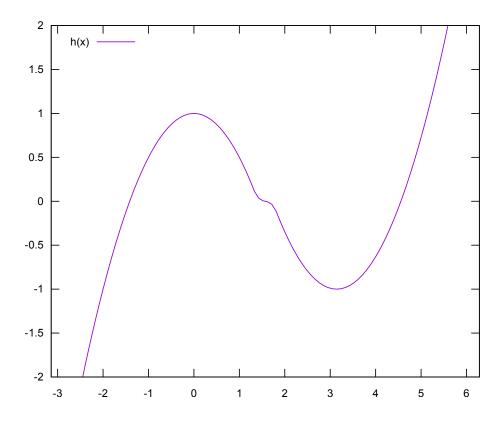

Figure 3.6.: Plot of h(x) with Hall joint

3.6.1. Implementation in Rust

In the program we can define a struct Joint that implements Func<f64, Complex64>. As in the example we need two functions f(x) and g(x) which we will rename to left and right. We will also need a variable α and δ which will be named cut and delta.

```
#[derive(Clone)]
 1
 2
    pub struct Joint {
 3
        pub left: Arc<dyn Func<f64, Complex64>>,
        pub right: Arc<dyn Func<f64, Complex64>>,
 4
 5
        pub cut: f64,
 6
        pub delta: f64,
 7
 8
 9
    impl Func<f64, Complex64> for Joint {
10
        fn eval(&self, x: f64) -> Complex64 {
            let chi = |x: f64| f64::sin(x * f64::consts::PI / 2.0).powi(2);
11
12
            let left_val = left.eval(x);
13
            return left_val + (right.eval(x) - left_val) * chi((x - self.cut) / self.
                delta)
14
```

In the proof we assume that f(x) and g(x) are continuous of first order in the interval $(\alpha, \alpha + \delta)$. In the code we will not check this requirement since it would have a major impact on performance to check the derivative on every point.

4. Calculation

4.1. Energy Levels

Solving the Schrödinger equation is an eigenvalue problem. This means that only certain energies will result in physically correct results. For an energy to be valid it has to satisfy the Maslov-corrected Bhor-Sommerfeld condition which states that

$$n \in \mathbb{N}_0 \tag{4.1}$$

$$C = \{ x \in \mathbb{R} \mid V(x) < E \} \tag{4.2}$$

$$C = \{x \in \mathbb{R} \mid V(x) < E\}$$

$$\int_{C} \sqrt{2m(E - V(x))} dx = 2\pi(n + 1/2)$$
(4.2)

this condition does not (in most cases) give the exact energy levels (Hall, 2013). It can be interpreted such that the oscillating part of the wave function has to complete all half oscillation.

To solve this problem for an arbitrary potential in a computer the set C and the fact that n has to be a non negative integer is not really helpful, but the condition can be rewritten to

$$p(x) = \begin{cases} \sqrt{2m(E - V(x))} & V(x) < E \\ 0 & else \end{cases}$$
 (4.4)

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} p(x)dx - \frac{1}{2} \mod 1 = 0 \tag{4.5}$$

Unfortunately 4.5 is not continuous which means that Newtons method can't be applied. Further on the bounds of integration have to be finite, this means the user of the program will have to specify a value for the constant APPROX INF where any value for x out side of that range should satisfy V(x) > E. But it shouldn't be to big since the integrate function can only evaluate a relatively small number (default 64000) of trapezes before the performance will suffer enormously. The default value for APPROX INF is (-200.0, 200.0).

The implementation is quite strait forward we evaluate 4.5 for a number of energies and then check for discontinuities.

```
pub fn nth energy<F: Fn(f64) -> f64 + Sync>(n: usize, mass: f64, pot: &F, view: (f64,
        f64)) -> f64 {
2
       const ENERGY STEP: f64 = 10.0;
3
       const CHECKS PER ENERGY STEP: usize = INTEG STEPS;
       let sommerfeld cond = SommerfeldCond { mass, pot, view };
4
5
6
       let mut energy = 0.0;
       let mut i = 0;
```

```
8
 9
        loop {
10
            let vals = evaluate function between(
11
                &sommerfeld cond,
12
                energy,
13
                energy + ENERGY STEP,
14
                CHECKS PER ENERGY STEP,
15
            );
16
            let mut int_solutions = vals
                 .iter()
17
18
                 .zip(vals.iter().skip(1))
                 .collect::<Vec<(&Point<f64, f64>, &Point<f64, f64>)>>()
19
20
                 .par_iter()
                 .filter(|(p1, p2)| (p1.y - p2.y).abs() > 0.5 || p1.y.signum() != p2.y.
21
                     signum())
22
                 .map(|ps| ps.1)
23
                 .collect::<Vec<&Point<f64, f64>>>();
24
            int solutions.sort by(|p1, p2| cmp f64(\&p1.x, \&p2.x));
25
            if i + int_solutions.len() > n {
26
                 return int solutions[n - i].x;
27
28
            energy += ENERGY_STEP - (ENERGY_STEP / (CHECKS_PER_ENERGY_STEP as f64 + 1.0))
29
            i += int solutions.len();
30
        }
31
    }
```

First we check over the interval $(0.0, ENERGY_STEP)$ if there are not enough zeros we check the next interval of energies and so on until we found n zeros. It's also possible that 4.5 is negative before the 0th energy there for we also have to check for normal zeros by comparing the signs of the values.

The struct SommerfeldCond is a Func<f64, f64> that evaluates 4.5.

4.1.1. Accuracy

For a benchmark we will use

$$m = 1$$

$$V(x) = x^{2}$$

$$(-\infty, \infty) \approx (-200, 200).$$

To get the actual values we will use Wolfram Language with WolframScript a programing language similar to Wolframalpha that can calculate the integral analytically. In Rust we can rewrite main to

```
1 fn main() {
2   let output_dir = Path::new("output");
3
```

```
4
        let values = (0..=50)
 5
            .into iter()
 6
            .map(|n: usize| Point::<usize, f64> {
 7
                y: energy::nth energy(n, 1.0, &potentials::square, APPROX INF),
 8
 9
            })
10
            .collect::<Vec<Point<usize, f64>>>();
11
12
        std::env::set_current_dir(&output_dir).unwrap();
13
        File::create("energy.txt")
14
            .unwrap()
            .write_all(plot::to_gnuplot_string(values).as_bytes())
15
16
17 }
```

This will output all energy levels from n = 0 to n = 50. We can implement the same thing WolframScript

```
m = 1
 1
 2
   V[x_{-}] = x^2
 3
 4
    nthEnergy[n ] = Module[{energys, energy},
 5
        sommerfeldIntegral[en] = Integrate[Sqrt[2*m*(en - V[x])],
 6
                                                 {x, -Sqrt[en], Sqrt[en]}]
        energys = Solve[sommerfeldIntegral[en] == 2*Pi*(n + 1/2), en] // N;
 7
 8
        energy = en /. energys[[1]];
 9
        energy
10
        ]
11
12
    energys = Table[\{n, N@nthEnergy[n]\}, \{n, 0, 50\}]
13
14 csv = ExportString[energys, "CSV"]
    csv = StringReplace[csv, "," -> " "]
16 Export["output/energies_exact.dat", csv]
```

These programs will output two files energy.txt (Appendix B.1) for our implementation in Rust and energies_exact.dat (Appendix B.1) for WolframScript. As a ruff estimate we would expect an error of $\pm \frac{10}{64000} \approx \pm 1.56 * 10^{-4}$, because the program checks for energies with that step size.

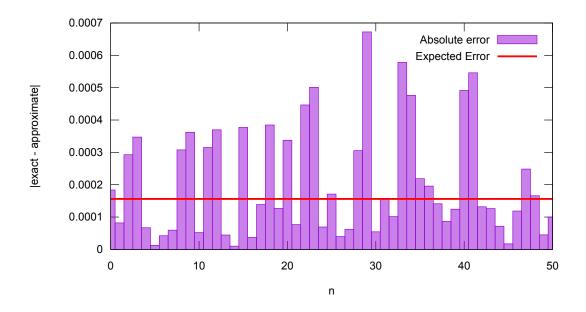

Figure 4.1.: Absolute error of energy levels in square potential

When we plot the absolute error we get figure 4.1.1. The error is a little higher than expected which is probably due to errors in the integral. Still the algorithm should be precise enough. If you'd like you could pick a lower value for ENERGY_STEP in src/energy.rs:49, but this will impact the performance for calculating energies with higher numbers for n.

4.2. Approximation Scheme

There are mainly three approximation methods used to solve for the actual wave function itself. There is perturbation theory which breaks the problem down in to ever smaller subproblems that then can be solved exactly. This can be achieved by adding something to the Hamiltonian operator \hat{H} which can then be solved exactly. But perturbation theory is inefficient compared to other approximation methods when calculated on a computer (Van Mourik et al., 2014, Introduction).

The second is Density functional field theory, it has evolved over the years and is used heavily in chemistry to calculate properties of molecules and is also applicable for the time dependent Schrödinger equation. It is something that might be interesting to add to the program in the future.

The program uses the third method WKB approximation, it is applicable to a wide verity of linear differential equations and works very well in the case of the Schrödinger equation. Originally it was developed by Wentzel, Kramers and Brillouin in 1926. It gives an approximation to the eigenfunctions of the Hamiltonian \hat{H} in one dimension. The approximation is best understood as applying to a fixed range of energies as \hbar tends to zero (Hall, 2013,

p. 305).

WKB splits $\Psi(x)$ into tree parts that can be connected to form the full solution. The tree parts are described as

$$p(x) = \sqrt{2m(|E - V(x)|)}$$
 (4.6)

$$V(t) - E = 0 \tag{4.7}$$

$$\psi_{exp}^{WKB}(x) = e^{\delta i} \frac{c_1}{2\sqrt{p(x)}} \exp\left(-\left|\int_x^t p(y)dy\right|\right)$$
(4.8)

$$\psi_{osz}^{WKB}(x) = \frac{c_1}{\sqrt{p(x)}} \exp\left(-\left|\int_x^t p(y)dy\right| i + \delta i\right)$$
 (4.9)

$$u_1 = -2m\frac{dV}{dx}(t) \tag{4.10}$$

$$\psi^{Airy}(x) = e^{(t-x+\delta)i} \frac{c_1 \sqrt{\pi}}{\sqrt[6]{u_1}} \text{Ai} \left(\sqrt[3]{u_1}(t-x)\right). \tag{4.11}$$

Since equation 4.7 might have more than one solution for turning points t, we have to consider each one of them individually and in the end join them into one function.

The factor of 1/2 in equation 4.8 is analogous to (Littlejohn, 2020, eq. 92). This means that it's only valid if the turning points aren't "too close together" (Littlejohn, 2020). This will be a problem later when we look at some solutions. Littlejohn (2020) also mansions that there are extensions to WKB that can handle these cases. It would be interesting to add those to the program in the future.

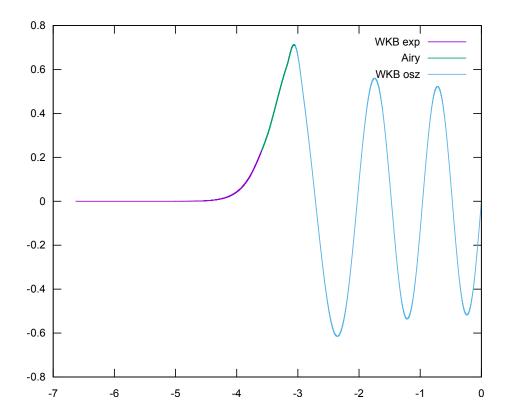

Figure 4.2.: Left half of wave function with $N_{Energy} = 5 \Rightarrow E = 11.0$, m = 2, $V(x) = x^2$

In figure 4.2 the three parts are visualized. The purple section on the left is the exponential decaying part $\psi^{WKB}_{exp}(x)$, equation 4.8 is a modified version of the original version as described in (Hall, 2013, p. 317, eq. 15.25) where b and a are different solutions for t of equation 4.7. The absolute symbol makes it possible to not differentiate between the case where x < t and x > t. Further on a factor of $e^{\delta i}$ was added such that the imaginary part of $\psi^{WKB}_{exp}(x)$ is the same as in $\psi^{WKB}_{osz}(x)$.

The blue part on the right is $\psi_{osz}^{WKB}(x)$. Again equation 4.9 was expanded to result in the more general complex solution and it also works for both ψ_1 and ψ_2 in (Hall, 2013, p. 316-317, Claim 15.7). Hall (2013) assumes that $\delta = \pi/4$ which doesn't work in the simple case of $V(x) = x^2$, in figure 4.2 $\delta = 0$ was used. This will be further discussed in section ??.

4.2.1. Validity

When we look at the derivation of WKB we will see that equations 4.8 and 4.9 can only be valid if

$$p(x) = \sqrt{V(x) - E}$$
$$\left| \frac{dp}{dx}(x) \right| \ll p^2(x)$$

as Zwiebach (2018) showed in his lecture. But this would mean that WKB is only valid iff V(x) > E because $p^2(x)$ would be negative otherwise. If this is the case this would imply that 4.8 can't be valid.

We will assume that this contradiction is wrong and assume that WKB is valid if

$$\left| \frac{d}{dx} (\sqrt{|V(x) - E|}) \right| < |V(x) - E|$$

4.2.2. Implementation

4.3. Turning Points

A point x where V(x) = E is called a turning point. We assume that the WKB function is a good approximation in the region where

$$-\frac{1}{2m}\frac{dV}{dx}(x) \ll (V(x) - E)^2. \tag{4.12}$$

In order to do the actual calculation we need a range were the Airy function is valid. From equation 4.12 we can infer that the Airy function is valid where

$$-\frac{1}{2m}\frac{dV}{dx}(x) - (V(x) - E)^2 > 0 {(4.13)}$$

We can assume that the Airy function is only valid in a closed interval, this means that there must be at least two roots of equation 4.13. These roots will be called turning point boundaries from now on.

The left boundary point must have a positive and the right a negative derivative. This means we can solve for roots and group them together by there derivatives.

In order to find all roots we will use a modification of Newtons method. When we find a solution, x_0 we can divide the original function by $(x-x_0)$ this means that Newtons method wont be able to find x_0 again.

Further on since we check for roots inside the interval of APPROX_INF we don't have a good first guess where the turning point might be. Because of this we will make 1000 guesses evenly distributed over the interval and invent a system that can rate how good of a guess this point could be. Newtons method works well if the value of f(x) is small and f'(x) is neither to small nor to big. We will assume that f'(x) = 1 is optimal. As a rating we will use

$$\sigma(x) = \frac{|f(x)|}{-\exp\left(\left(\frac{df}{dx}(x)\right)^2 + 1\right)}$$

where lower is better. This function is just an educated guess, but it has to have some properties, as the derivative of f tends to 0, $\sigma(x)$ should diverge to infinity.

$$\lim_{\frac{df}{dx}\to 0} \sigma(x) = \infty$$

If f(x) = 0 we found an actual root in the first guess meaning that $\sigma(x)$ should be 0. Formula 4.3 doesn't satisfy this property since it's undefined if f'(x) = 0 and f(x) = 0, but we can extend it's definition such that

$$\sigma(x) = \begin{cases} \frac{|f(x)|}{-\exp(\left(\frac{df}{dx}(x)\right)^2 + 1)} & f(x) \neq 0 \text{ and } \frac{df}{dx} \neq 0\\ 0 & \text{else} \end{cases}$$

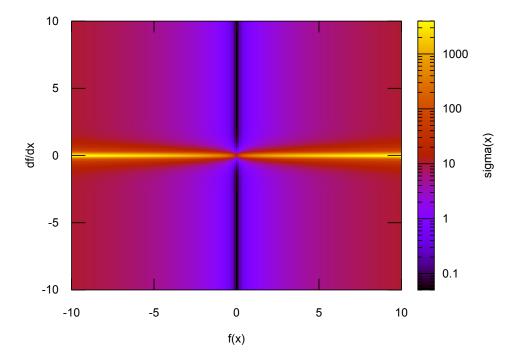

Figure 4.3.: Logarithmic heat diagram of $\sigma(x)$, darker/bluer is better

As we can see in figure 4.3 where darker/bluer values are better than yellow/red areas that $\sigma(x)$ indeed has all of the desired properties.

After we rated all of the 1000 guesses we can pick the best one as a first guess and use the modified Newtons method with it. We do this process 256 times by default. In theory we could therefor use the WKB approximation for potentials with up to 256 turning points.

```
1 fn find_zeros(phase: &Phase, view: (f64, f64)) -> Vec<f64> {
2    let phase_clone = phase.clone();
3    let validity_func = Arc::new(move |x: f64| {
```

```
4
            1.0 / (2.0 * phase clone.mass).sqrt() * derivative(&|t| (phase clone.
                 potential)(t), x).abs()
 5
                 - ((phase clone.potential)(x) - phase clone.energy).pow(2)
 6
        });
 7
        let mut zeros = NewtonsMethodFindNewZero::new(validity func, ACCURACY, 1e4 as
            usize);
 8
 9
        (0..MAX_TURNING_POINTS).into_iter().for_each(|_| {
10
            let modified_func = |x| zeros.modified_func(x);
11
12
            let guess = make_guess(&modified_func, view, 1000);
13
            guess.map(|g| zeros.next_zero(g));
14
        });
15
        let view = if view.0 < view.1 {</pre>
16
17
            view
18
        } else {
19
            (view.1, view.0)
20
        let unique_zeros = zeros
21
22
             .get previous zeros()
23
             .iter()
             .filter(|x| **x > view.0 \&\& **x < view.1)
24
25
             .map(|x| *x)
26
             .collect::<Vec<f64>>();
27
        return unique_zeros;
28
    }
```

Here make_guess uses $\sigma(x)$ and returns the best guess. NewtonsMethodFindNewZero is the modified version of Newtons method where all the roots are stored and its implementation of Func<f64, f64> is just defined as

$$\frac{f(x)}{\prod\limits_{r\in Z}(x-r)}\tag{4.14}$$

Where the set Z is the set of all the zeros that have been found previously. After the 256 iterations we filter out all the zeros that aren't in the view. Equation 4.14 is implemented in NewtonsMethodFindNewZero. Unfortunately this procedure can't be implement asynchronously since you have to know all previous zeros before you can find a new one.

Once we found the zeros we need to group them as previously mentioned the derivative of the validity function (4.13) must be positive if the boundary point is on the left and negative when its on the right side of the turning point. It could be the case that if the turning point is in the view that one of the boundary points is actually outside the view. For this we can use Regula falsi combined with bisection. We will do this for both the left and right most turning point if there was only one boundary found.

4.4. Wave Function

To combine all of the different wave function parts we will create the WaveFunction struct. First lets define the WaveFunctionPart trait.

```
pub trait WaveFunctionPart: Func<f64, Complex64> + Sync + Send {
    fn range(&self) -> (f64, f64);
    fn as_func(&self) -> Box<dyn Func<f64, Complex64>>;
4 }
```

All that we need is a range in which the function is valid. Also (Hall, 2013, p. 317) states that the oscillating parts of WKB might have to negated, because of this we will also introduce the WaveFunctionPartWithOp trait. In addition to the wave function itself it will also store and operation as negate for example.

The two functions as wave function part and as func are to emulate trait up casting because in the current version of Rust this is still an experimental feature.

ApproxPart will be the implementation of WaveFunctionPartWithOp that handles a wave function part that contains a AiryWaveFunction and a WkbWaveFunction. As suggested by Hall (2013) we will add joints between the WKB and Airy functions.

PureWkb can be used if there are no turning points. It just stores a WkbWaveFunction. This version is just for completeness since it might be very inaccurate to only use a WKB function. This functionality was just introduced for completeness.

To construct a new WaveFunction we will first calculate the energy with energy::nth_energy. After this we can calculate the new view by running Newtons method on V(x)-E to find the outer most turning points, then the view will be defined by t * view_factor where t is the turning point.

Once we've calculated the view, we can calculate all the turning points with the AiryWaveFunction constructor that will also give us all the Airy parts we will need later. If there were no turning points found in the view we can construct two WkbWaveFunction and connect them in the middle of the view. Because the sign of the wave function might not match have to find a the best operation from

This will be done in the find_best_op function where we choose the operation that has the minimal error both with respect to the derivative and the value of the wave function. Mathematically we choose the operation o(x) for which

$$|o(\psi_0(x)) - \psi_1(x)|^2 + \left|o\left(\frac{d}{dx}\psi_0(x)\right) - \frac{d}{dx}\psi_1(x)\right|^2$$

is minimal, $\psi_0(x)$ is the wave function to the left and $\psi_1(x)$ is the wave function to the right of the middle of the view. The next step is to introduce joints in the middle of the view. After this we end up with the whole wave function.

In the other case where there actually are turning points, we will iterate over all of them and construct a ApproxPart from them. In order to define a range for the ApproxPart we will add two more turning points at APPROX_INF.0 and APPROX_INF.1 Then we can iterate over all the turning points in triplets and construct a WkbWaveFunction at the middle turning point. Once we've constructed all the WkbWaveFunctions we can combine them with the AiryWaveFunctions to construct the ApproxParts Just like in the case with no turning points we have to find an operation for each ApproxPart using the find_best_op_wave_func_part function.

In case $ENABLE_WKB_JOINTS$ is true we also have to introduce joints between all the ApproxPart s.

It has previously been mentioned that $\delta=\pi/4$ does not work for all potentials. An attempt to correct this is implemented in the calc_phase_offset function. When we consider the point where two WkbWaveFunction meet the condition

$$\exp\left(i\int_{x}^{t_0} \sqrt{2m(|E-V(y)|)} dy + i\delta\right) = \exp\left(i\int_{x}^{t_1} \sqrt{2m(|E-V(y)|)} dy - i\delta\right)$$

has to hold for both turning points t_0 and t_1 . To make it simpler lets use

$$a = \int_{x}^{t_0} \sqrt{2m(|E - V(y)|)} dy$$
 (4.15)

$$b = \int_{x}^{t_1} \sqrt{2m(|E - V(y)|)} dy$$
 (4.16)

therefor

$$e^{(a+\delta)i} = e^{(b-\delta)i}.$$

When we solve for δ we get

$$\delta = \frac{b-a}{2}.$$

Unfortunately according to Hall (2013) this solution might not be valid in terms of the Airy functions and it should be further investigated why $\delta = \pi/4$ does not work in some cases. But at the time of writing this document no explanation has been found yet.

Finally since the Schrödinger equation is linear the user can choose from 3 types of scaling. Where $a \in \mathbb{C}$.

None The solution wont be multiplied by anything.

Mul(a) The solution will be multiplied by a.

Renormalize(a) $\Psi(x)$ will be renormalized such that $\int_{-\infty}^{\infty} |a\Psi(x)|^2 dx = 1$. This can be useful to add a phase to the wave function.

4.5. Super Position

Because the super position principal is also applicable to energies it is possible that $\Psi(x)$ is a sum of wave functions with different energies.

On the implementation side this means that we can create a struct SuperPosition that is constructed with a list of energy levels and ScalingType that can be used to construct the previously discussed WaveFunction. Its implementation of Func<f64, Complex64> will then sum over all the results of the individual WaveFunction structs.

5. Program Manual

In the src directory you will find the main.rs file. After the imports (lines with use) you can find all the constants that can be configured. In the description below, (E) stands for "expert" and means that you should use the default unless you really know what you're doing.

Concurrency Configurations Tune accuracy and performance

- **INTEG STEPS** The number of steps that will be used to integrate over an interval
- **TRAPEZE_PER_THREAD (E)** The number of trapezes that are calculated on a thread in sequence. This number must be smaller then INTEG STEPS.
- **NUMBER_OF_POINTS** The number of points that will be written to the output file.
- **APPROX_INF** This are the values for " $\pm \infty$ ". Where the first number is $-\infty$ and the second number is ∞ . Most importantly outside of this interval V(x) > E.

Joint configuration Adjust the width of joints

- **AIRY_TRANSITION_FRACTION (E)** When a joint between an Airy and a WKB function has to be added, we have to know how wide the joint should be. The width is calculated by taking the distance between the turning point boundaries and multiplying it by this number.
- WKB_TRANSITION_FRACTION (E) Same as the previous option just at the boundary between two WKB parts. It takes the width of the whole WKB part and multiplies it by this number to get the width of the joint.
- **ENABLE_WKB_JOINTS** If set to true joints will be added between WKB wave function parts. If set to false no joints will be added at this boundary. false is recommended when plotting probabilities.
- **ENABLE_AIRY_JOINTS** If set to true joints will be added at the boundary between Airy and WKB functions. false no joints will be added at these boundaries.
- **Complex Results** Since Hall (2013) does not work with complex numbers you might get better results when setting all options to false.
 - **COMPLEX_AIRY** If set to true the airy function will output complex numbers. This setting is recommended when using plot_3d.gnuplot. false only real values will be outputted. Recommended when using plot.gnuplot.
 - **COMPLEX_EXP_WKB** If set to true the exponential WKB part will output complex numbers. This setting is recommended when using plot_3d.gnuplot. false only real values will be outputted. Recommended when using plot.gnuplot.

COMPLEX_OSZ_WKB If set to true the oscillating WKB part will output complex numbers. This setting is recommended when using plot_3d.gnuplot. false only real values will be outputted. Recommended when using plot.gnuplot.

5.1. Wave Function

When you only have one energy level you should use WaveFunction::new.

```
let wave_function = wave_function_builder::WaveFunction::new(
    &/*potential*/,
    /*mass*/,
    /*nth energy*/,
    APPROX_INF,
    1.5,
    ScalingType::/*Scaling*/,
);
```

The example above has to placed right after the fn main() line. You have to replace all the commentaries (/*...*/) with the values you want. For the first you can choose a potential from section 5.4 for this you can type potentials::/*potential*/.

For the Mass you can just use a normal float.

"nth energy " must be a positive integer (including 0) and is the nth energy level of the potential.

And as for the scaling type, choose one of the options described at the end of section 4.4.

5.2. SuperPosition

To construct a super position you can add this to your main function

```
1
    let wave function = wave function builder::SuperPosition::new(
 2
        &/*potential*/,
 3
        /*mass*/,
 4
        []&
 5
            (/*nth energy*/, /*phase*/),
            (/*nth energy*/, /*phase*/),
 6
 7
 8
        ],
 9
        APPROX INF,
10
        1.5, // view factor
11
        ScalingType::/*scaling*/),
12);
```

Just like in section 5.1 you have to replace all the commentaries (/*...*/) with the values you want.

[&]quot;potential" you have to choose a potential from section 5.4.

[&]quot;mass" your mass as a float.

[&]quot;nth energy" must be a positive integer (including 0) and is the nth energy level of the

potential.

"phase" a complex number that the wave function with the corresponding energy will be multiplied by. To make a complex number you can use complex(/*Re*/, /*Im*/).

"// ..." you can add as many energies as your computer can handle.

And as for the scaling type, choose one of the options described at the end of section 4.4.

5.3. Plotting

For all the plotting methods mentioned below you'll need an output directory in which the files will be placed.

```
1 let output dir = Path::new("output");
```

The default is *output*, you can choose any directory name that you'd like. The folder will be located where you ran the program. The data calculated by the program will be stored as space separated values like in the example below (the first line will not be in the output file).

```
x Re Im
1.0 2.718 3.141
2.0 1.414 1.465
```

Every line is a data point where the first number is the x-coordinate, the second the real part of $\Psi(x)$ and the third the imaginary part of $\Psi(x)$

5.3.1. WaveFunction

For a WaveFunction as we've seen in section 5.1 you have three options.

plot wavefunction

With plot::plot_wavefunction the result will be plotted as one function in gnuplot.

```
1 plot::plot wavefunction(&wave function, output dir, "data.txt");
```

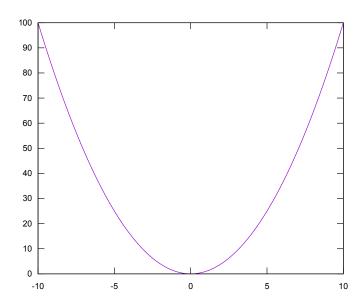

You can replace *data.txt* with another file name.

plot_wavefunction_parts
plot_probability

5.4. Potentials

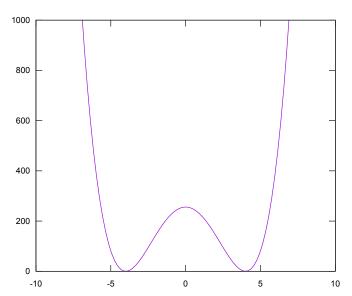

square Normal square potential as used in Hall (2013).

 x^2

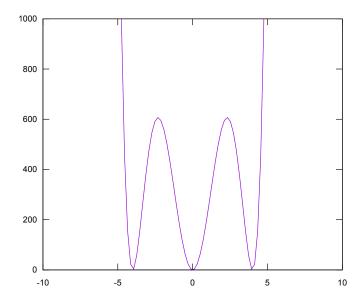

mexican_hat 4th degree polynomial that looks like a mexican hat, with 2 minima.

$$(x-4)^2(x+4)^2$$

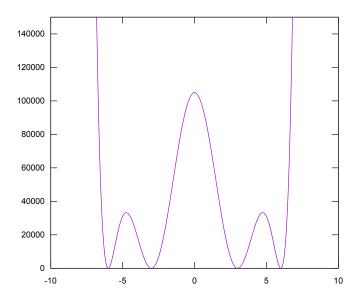

double _mexican _hat 6th degree polynomial that has 3 minima.

$$(x-4)^2x^2(x+4)^2$$

triple_mexican_hat 8th degree polynomial that has 4 minima.

$$(x-6)^2(x-3)^2(x+3)^2(x+6)^2$$

smooth_step Step function that goes to ENERGY_INF outside the interval (-5,5). Joints were added at ± 5 to make the function differentiable.

5.4.1. Custom Potentials

To create a custom potential you'll have to define a function like shown below.

```
1 fn my_potential(x: f64) -> f64 {
2    return /*some calculation*/;
3 }
```

my_potential is the name that you can choose and have to use later when you're passing it to WaveFunction::new. /*some calculation*/ can be any Rust code that results in a f64.

Examples

Negative bell curve $(-e^{-x^2} + 1)$

```
1 fn neg_bell(x: f64) -> f64 {
2    return -(-x.powi(2)).exp();
3 }
```

General polynomial (might not work for all configurations)

```
1 const COEFFICIENTS: [f64;4] = [a, b, c, d]
2 fn polynom(x: f64) -> f64 {
```

You need to set values for a, b, etc. and they need to be floating point numbers or you'll get error E0308. For example 1 would cause an error but 1.0 or 3.141 are correct. You can add even more coefficients if you'd like. The 4 in the square brackets is the degree of the polynomial plus 1. The potential above would mathematically be $a + bx + cx^2 + dx^3$.

A. Detailed Calculations

A.1. Proofs

A.1.1. Smoothness of Transitionfunction

Given that

$$f: \mathbb{R} \to \mathbb{C} \tag{A.1}$$

$$g: \mathbb{R} \to \mathbb{C}$$
 (A.2)

$$\{f,g\} \in C^1 \tag{A.3}$$

$$\{\alpha, \delta\} \in \mathbb{C} \tag{A.4}$$

define (Hall, 2013)

$$\chi(x) = \sin^2\left(\frac{\pi(x-\alpha)}{2\delta}\right) \tag{A.5}$$

$$(f \sqcup g)(x) = f(x) + (g(x) - f(x))\chi(x)$$
(A.6)

and proof that

$$\frac{d(f \sqcup g)}{dx}(\alpha) = \frac{df}{dx}(\alpha) \tag{A.7}$$

$$\frac{d(f \sqcup g)}{dx}(\alpha + \delta) = \frac{dg}{dx}(\alpha + \delta). \tag{A.8}$$

Calculate derivatives

$$\frac{d\chi}{dx}(x) = \frac{\pi}{2\delta} \sin\left(\frac{\pi(x-\alpha)}{\delta}\right) \tag{A.9}$$

$$\frac{d(f \sqcup g)}{dx}(x) = \frac{df}{dx}(x) + \left(\frac{dg}{dx}(x) - \frac{df}{dx}(x)\right)\chi(x) + (g(x) - f(x))\frac{d\chi}{dx}(x). \tag{A.10}$$

Note that

$$\frac{d\chi}{dx}(\alpha) = 0 \tag{A.11}$$

$$\chi(\alpha) = 0 \tag{A.12}$$

$$\frac{d\chi}{dx}(\alpha+\delta) = 0 \tag{A.13}$$

$$\chi(\alpha + \delta) = 1 \tag{A.14}$$

therefor

$$\frac{d(f \sqcup g)}{dx}(\alpha) = \frac{df}{dx}(\alpha) + 0\left(\frac{dg}{dx}(\alpha) - \frac{df}{dx}(\alpha)\right) + 0(g(x) - f(x)) = \frac{df}{dx}(\alpha) \tag{A.15}$$

and

$$\frac{d(f \sqcup g)}{dx}(\alpha + \delta) = \frac{df}{dx}(\alpha + \delta) + 1\left(\frac{dg}{dx}(\alpha + \delta) - \frac{df}{dx}(\alpha + \delta)\right) + 0(g(x) - f(x)) \quad (A.16)$$

$$\frac{d(f \sqcup g)}{dx}(\alpha + \delta) = \frac{df}{dx}(\alpha + \delta) + \frac{dg}{dx}(\alpha + \delta) - \frac{df}{dx}(\alpha + \delta) = \frac{dg}{dx}(\alpha + \delta) \blacksquare. \quad (A.17)$$
